AGRADECIMENTOS

Ao Museu Paraense Emílio Goeldi pela infraestrutura fornecida desde a iniciação científica, iniciada em agosto de 2013, até o presente momento no final do mestrado, fevereiro de 2020.

Ao programa de Pós-graduação em Ciências Biológicas – Botânica Tropical, do Museu Paraense Emílio Goeldi e Universidade Federal Rural da Amazônia, pela oportunidade do desenvolvimento deste estudo.

Ao Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPQ, pela concessão da bolsa e a Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil – CAPES, pelo financiamneto (Código 001).

Admiração, carinho e muito respeito a Dra. Anna Luiza Ilkiu-Borges, por todos esses anos trabalhando juntos, adquirindo muito conhecimento científico e conhecimento de vida, construindo uma amizade, e reconhecendo todo tipo de apoio e ajuda.

Ao Prof. Dr. Robbert Gradstein pelas correções, envio de amostras do exterior, ajuda e apoio no desenvolvimento deste trabalho.

Aos curadores dos herbários brasileiros e estrangeiros (ALCB, BM, G, HBRA, ICN, INPA, JE, MG, NICH, NY, RB, S, SP e UFP) pelo envio de amostras de *Radula* coletadas no Brasil e tipo nomenclaturais.

À Dra. Barbara Thiers pelo apoio logístico durante a visita ao New York Botanical Garden, com livre acesso ao herbário e àquela instituição.

À M.Sc. Laura Briscoe por toda a ajuda prestada durante os trabalhos no herbário NY, facilitando sobremaneira minhas atividades durante a visita ao New York Botanical Garden.

Ao Dr. William Buck pelo apoio e esclarecimentos acerca do tipo de *Radula yanoella*.

À Dra. Rafaela Forzza pela autorização e apoio durante a visita ao herbário RB do Jardim Botânico do Rio de Janeiro.

À equipe passada (Eliene, Sirlene, Gabriela, Eliete, Monique, Aline, Eline) e atual (Luciana e Jean) do Laboratório de Briologia por toda ajuda no conhecimento sobre as briófitas, experiencias repassadas, conversas e entre outros.

À Eliene Lima, Karen Lameira, Jean César e Fabio Araújo pela amizade, conversas e ajuda tanto no mestrado como na vida.

A minha família, em especial meus pais Rubens Soares da Silva e Silvana Maria Oliveira da Silva e aos meus irmãos, Fabrycio e Fernanda.

E a todos que contribuíram direta ou indiretamente para o meu trabalho.

Obrigado!

RESUMO

Radula Dumort. é o único gênero de Radulaceae com 200-250 espécies distribuídas no mundo, apresentando maior diversidade nas regiões tropicais e subtropicais. As plantas desse grupo são reconhecidas pela presença dos ramos do tipo-*Radula*, filídios íncubos, anfigastros ausentes, presença de rizoides em tufo na superfície do lóbulo e perianto tubular, achatado dorsoventralmente. O objetivo deste trabalho é realizar um estudo taxonômico do gênero *Radula* no Brasil baseado em caracteres morfológicos e na observação de espécimes tipos e espécimes adicionais depositados em herbários. No total, foram reconhecidas 31 espécies e duas variedade de *Radula* no país. Foram descritas três espécies novas e uma variedade nova para a ciência: *Radula bahiensis*, *R. yamadae*, *R. renneri*, e *R. fendleri* var. paroica. Foram registradas três novos ocorrências para o Brasil, incluindo *Radula longiloba*, *R. punctata* e *R. xalapensis*, duas espécies são confirmadas para o Brasil, *R. pseudostachya* e *R. subinflata*, três espécies tiveram seus registros excluídos no país, *R. ellottii*, *R. varilobula* e *R. wrightii*, e três espécies foram classificadas como duvidosas, *R. marginata*, *R. microloba* e *R. saccatiloba*. Seis lectótipos para *Radula flaccida*, *R. epiphylla* (=*R. flaccida*), *R. quadrata*, *R. tectiloba*, *R. tenera* e *R. stenocalyx* e um neótipo para *R. yanoella* foram designados. *Radula obovata* é proposta como um sinônimo novo para *R. pallens*. Neste estudo é fornecida uma chave dicotómica, descrições, ilustrações taxonômicas, comentários sobre a distribuição geográfica e ecológica para todas as espécies de *Radula* registradas no Brasil.

Palavras-chaves: Hepáticas folhosas, briófitas, taxonomia.

ABSTRACT

Radula Dumort. is the only genus of Radulaceae with 200-250 species distributed worldwide, with high diversity in tropical and subtropical regions. The plants of this group are recognized by the presence of *Radula*-type branches, incubus leaves, underleaves absent, presence of rhizoids in tufts on the lobule surface and perianth tubular, dorsiventrally flattened. The objective of this work is to carry out a taxonomic study of the genus *Radula* in Brazil based on morphological characters and on the observation of type specimens and additional specimens deposited in herbaria. In total, 31 species and two varieties of *Radula* were recognized in the country. Three new species and one new variety to science were described: *Radula bahiensis*, *R. yamadae*, *R. renneri*, and *R. fendleri* var. *paroica*. Three new occurrences were registered for Brazil, including *Radula longiloba*, *R. punctata* and *R. xalapensis*, two species are confirmed for Brazil, *R. pseudostachya* and *R. subinflata*, three species had their records excluded in the country, *R. ellottii*, *R. varilobula* and *R. wrightii*, and three species were classified as doubtful, *R. marginata*, *R. microloba* and *R. saccatiloba*. Six lectotypes for *Radula flaccida*, *R. epiphylla* (=*R. flaccida*), *R. quadrata*, *R. tectiloba*, *R. tenera* and *R. stenocalyx* and one neotype for *R. yanoella* were assigned. *Radula obovata* is proposed as a new synonym for *R. pallens*. In this study a dichotomous key, descriptions, taxonomic illustrations, comments on the geographic and ecological distribution for all *Radula* species recorded in Brazil are provided.

Keywords: Leafy liverworts, bryophytes, taxonomy.

CONTEXTUALIZAÇÃO

Radula Dumort. pertencente a Radulaceae Müll. Frib. e inclui 246 espécies no globo, com grande diversidade nas regiões tropicais e subtropicais (SCHUSTER, 1980b; YAMADA, 1979; SÖDERSTRÖM *et al.*, 2016).

Os membros de *Radula* ocorrem geralmente sobre troncos de árvores vivas, árvores mortas e folhas, ocasionalmente sobre rocha e solo (GRADSTEIN *et al.*, 2001; DEVOS *et al.*, 2011b). Apresentam características singulares que os distinguem dos demais grupos, principalmente pela (1) presença de ramos do tipo-*Radula* (ramo que se origina de uma célula epidérmica do caulídio e, portanto, associado a um filídio não modificado); (2) filídios íncubos; (3) ausência de anfigastros, (4) rizóides em tufo na superfície do lóbulo e (5) e pelo perianto tubular, dorsiventralmente achatado (SCHUSTER, 1980b; GRADSTEIN *et al.*, 2001; CRANDALL-STOTLER *et al.* 2009).

Todavia, outras características são relevantes para a identificação das espécies, como a ornamentação das células do corte transversal do caulídio (células epidérmicas e medulares), tipo, ausência ou presença e posição das gemas, ornamentação das células da superfície da cápsula, forma e tipo de inserção do lóbulo, e morfologia do perianto e do esporo (JONES, 1977; SCHUSTER, 1980B; RENNER & BRAGGINS, 2004; 2005).

Dumortier (1822) introduziu o gênero baseado em oito espécies de Linnaeus (separadas dos demais gêneros de hepáticas pelo perianto compresso, com rosto largo, não se estreitando no ápice), incluindo *Jungermannia complanata* L. [= *Radula complanata* (L.) Dumort.], que foi conservado como o tipo do gênero *Radula* (GROLLE, 1983). Grolle (1969) discutiu brevemente a tipificação de *R. complanata* e designou o espécime em Herb. Dillenius (OXF) como o lectótipo.

As primeiras classificações para o gênero foram publicadas por Stephani (1884) e Spruce (1884). Stephani (1884) dividiu 92 espécies em 12 seções e utilizou características morfológicas e ecológicas para defini-las. Essa classificação foi artificial e projetada exclusivamente para facilitar a identificação das espécies (SCHUSTER, 1980a).

Spruce (1884) propôs o subgênero *Cladoradula* somente para a espécie *Radula gottscheana* Taylor, a qual não apresentava inovações subflorais e apresentava cápsulas esféricas. As 12 espécies restantes do estudo de Spruce (1984) foram alocadas no subgênero *Acroradula*.

Na importante obra “*Species Hepaticarium*” de Stephani (1910), foram registradas 220 espécies de *Radula* divididas em sete seções (Acutifolia, Appendiculatae, Ampliatae, Communes,

Microlobae, *Longilobae*, *Amentulosae*), com base na ecologia e principalmente na morfologia do lóbulo das plantas.

Um dos cientistas mais importantes que realizou estudos taxonômicos das espécies de *Radula* foi Hampstead Castle. Inicialmente, Castle (1925) revisou o gênero *Radula* para os Estados Unidos e Canadá, registrando 11 espécies. Posteriormente, o mesmo autor publicou 11 artigos de revisão taxonômica em nível mundial para 217 espécies, divididos em duas partes. A primeira parte estava relacionado as espécies do subgênero *Cladoradula* (CASTLE, 1937) e a segunda parte, reuniu as seções *Epiphyllae* (CASTLE, 1939), *Amentulosae* (CASTLE, 1950), *Dichotomae* (CASTLE, 1959a), *Marginatae* (CASTLE, 1959b), *Lingulatae* (CASTLE, 1962), *Saccatae* (CASTLE, 1963), *Acutilobulae* (CASTLE, 1964), *Densifoliae* (CASTLE, 1965), *Ampliatae* (CASTLE, 1966) e *Complanatae* (CASTLE, 1967), pertencentes ao subgênero *Acroradula*. Nesses trabalhos, Castle aceitou algumas seções propostas por Stephani (1910).

Grolle (1970) propôs uma nova espécie (*Radula castlei* Grolle) e realizou algumas correções nomenclaturais das seções propostas nos trabalhos de Castle. Além disso, foram determinadas duas novas seções para a subgênero *Cladoradula* (*Cladoradula* e *Campanigerae*), ficando, o gênero *Radula*, com um total de dois subgêneros e 13 seções.

Um estudo das espécies de *Radula* Africanas realizado por Jones (1977) classificou o gênero em uma forma infragenérica em cinco grupos. Os grupos eram diferenciados pelo corte transversal do caulídio, hábitos, cutícula dos filídios, esporos e o tipo de perianto. Todavia, o autor não deu nomes válidos aos grupos por considerar que mais espécies de *Radula* de outras regiões fitogeográficas deviam ser examinadas e estudadas. Jones (1977) discute que as seções dos trabalhos de Stephani e Castle eram claramente artificiais, na medida em que separaram amplamente espécies que são intimamente associadas a ponto de serem sinônimos.

Outro estudo importante sobre *Radula* foi o de Yamada (1979), no qual registrou ca. 350 espécies asiáticas, estabeleceu o subgênero *Odontoradula* (baseado nas espécies com lóbulos inseridos transversalmente ou obliquamente no caulídio e pela presença de inovações subflorais), e reconheceu nove seções dentro do subgênero *Radula*. Este mesmo autor dedicou-se também a revisar as espécies tipo do gênero que ocorrem na América Latina, publicando descrições e ilustrações de espécies e propondo vários novos sinônimos (YAMADA, 1980; 1981; 1982a; 1987a; 1991; 1993a).

Desde a década de 80, Kohsaku Yamada dedicou-se aos estudos do gênero *Radula* em várias regiões do mundo, como Nova Caledônia (Yamada 1985a), Queensland (Austrália) (YAMADA, 1984; 1987b), Península de Huon (Papua-Nova Guiné) (YAMADA & PIPPO, 1989a), Monte Kinabuli (Malásia) (YAMADA, 1989b), Ilha de Galapagos (Equador) (YAMADA

& GRADSTEIN, 1991), Zaire e Rwanda (África) (YAMADA, 1993b), Japão (YAMADA, 1996), Brasil (YAMADA, 2003).

Todos esses estudos e investigações taxonômicas resultaram em registros de várias novas espécies para a ciência (YAMADA, 1982b; 1982c; 1982d; 1983; 1985b; 1990; 1995), e algumas importantes para a América Latina, registradas principalmente no Brasil e em Cuba, como *Radula schaefer-verwimpii* K.Yamada, *R. cubensis* K.Yamada, *R. longiloba* K.Yamada, *R. pocsii* K.Yamada e *R. tenuis* K.Yamada.

Após a revisão de Yamada (1979), Schuster (1980a) publicou o primeiro estudo filogenético da subordem Radulineae R.M.Shust. Schuster (1980a) apresentou de forma detalhada alguns critérios taxonômicos e propôs o subgênero *Metaradula* e 21 seções dentro dos quatro subgêneros conhecidos para *Radula*. No mesmo ano, Schuster (1980b) descreveu as espécies de *Radula* da América do Norte e estabeleceu diagnósticos e correções para as espécies citadas em seu estudo anterior.

Yamada & Piippo (1989) propuseram uma nova seção (Caducae Schust. ex Yamada & Piippo), três novas subseções, cinco combinações de subseções, e 10 novas espécies descritas.

Trabalhos realizados na América do Sul, foram de suma importância para o conhecimento e identificação do gênero como os de Reiner-Drehwald (1994), Gradstein *et al.* (2001), Yamada (2003) e Gradstein & Ilkiu-Borges (2009). Esses autores realizaram tratamentos taxonômicos de *Radula* para a Argentina, América Tropical, Brasil e Guiana Francesa, respectivamente, citando novas ocorrências e excluindo alguns nomes citados erroneamente para o local de estudo.

Na classificação geral das hepáticas de Crandall-Stotler *et al.* (2009), o gênero *Radula* está inserido na ordem Porellales Schljakov, subordem Radulineae R.M.Schust. e na família Radulaceae Müll. Frib. O mais recente estudo que tratou da filogenia de *Radula*, com base nas características moleculares, reconheceu três novos subgêneros dentre os já conhecidos (Devos *et al.* 2011a). *Radula* passou então a contar com sete subgêneros, sendo que apenas os cinco primeiros ocorrem no Brasil: *Metaradula* R.M.Schuster, *Volutoradula* Devos *et al.*, *Radula*, *Odontoradula* Yamada, *Cladoradula* Spruce, *Amentuloradula* Devos *et al.* e *Dactyloradula* Devos *et al.*

No Brasil, Radulaceae é a quinta maior família de hepáticas com 26 espécies registradas, sendo uma espécie endêmica (*Radula brasiliaca* K.Yamada), ficando atrás somente de Lejeuneaceae (285 espécies), Lepidoziaceae (48 espécies), Frullaniaceae (37 espécies) e Ricciaceae (36 espécies) (COSTA & PERALTA, 2015).

Radula complanata (L.) Dumort. e *R. pallens* (Sw.) Mont. foram as primeiras espécies registradas no Brasil por Raddi (1823), como *Candollea complanata* (L.) Raddi e *Jungermannia*

pallens Sw., respectivamente. No entanto, os espécimes de Raddi foram recentemente estudados por Costa (2009), que descobriu que àquele identificado como *R. complanata* pertence à *Radula voluta* Taylor. A coleção identificada como *R. pallens* não foi localizada.

Outros estudos no país registraram diferentes espécies de *Radula*, ampliando a riqueza para o gênero, como os trabalhos de Nees (1833), Spruce (1884), Stephani (1910), Dusén (1903), Castle (1959, 1962, 1963 e 1964), Schiffner & Arnell (1964), entre outros.

Oliveira (1973) foi o primeiro estudo de *Radula* realizado no Brasil, no estado do Rio Grande do Sul, que ilustrou o hábito, comentou sobre o gênero e apresentou uma breve descrição na chave com oito espécies de *Radula*.

Yano (1984) compilou dados de estudos e publicou um *checklist* de hepáticas e antóceros brasileiros, onde registrou 29 espécies de *Radula*. Depois disso, outros *checklists* de Yano (1989, 1995) adicionaram mais duas e oito espécies, respectivamente, totalizando 39 espécies de *Radula* no Brasil.

Yamada (2003) apresentou uma chave de identificação, comentários morfológicos, distribuição e ilustração para 27 espécies de *Radula* no Brasil [excluindo *R. boryana* (Weber) Nees ex Mont. e *R. complanata* (L.) Dumort.]. Posteriormente, Yano (2008) registrou 44 espécies de *Radula* em um novo catálogo para o Brasil, considerando algumas não registradas ou excluídas por Yamada (2003).

Tendo em vista o grande número de espécies de *Radula* que ocorrem no Brasil (quinto maior gênero), o conhecimento disperso em várias obras e, ainda, a dificuldade em reconhecer e identificar a maioria das espécies, um estudo taxonômico, incluindo a análise de tipos nomenclaturais, direcionado ao entendimento e circunscrição das espécies do gênero *Radula* no Brasil se faz necessário.

Esta dissertação abrange quatro capítulos: o primeiro *Discovery of genuine Radula complanata (L.) Dumort. in Brazil*, submetido à revista Rodriguésia; o segundo capítulo compreende a descrição de uma nova espécie e uma nova variedade, intitulado *A new species and new variety of Radula Dumort. (Radulaceae, Machantiophyta) from Brazil*, submetido à revista Phytotaxa; o terceiro capítulo, também trata da descrição de uma espécie nova, intitulado *On a new species of Radula Dumort. (Radulaceae, Machantiophyta) from mountain ranges in the Atlantic Forest, Brazil*, submetido à revista Nova Hedwigia; O quarto capítulo, que também será submetido à revista Phytotaxa, compreende a revisão das espécies do gênero no Brasil, intitulado *Taxonomic study of Radula Dumort. (Radulaceae, Machantiophyta) in Brazil*.

Abstract

In the course of a taxonomic study of *Radula* in Brazil, a new species from Bahia and a new variety of *R. fendleri* from Rio de Janeiro were detected. The new species is characterized by plants irregularly pinnate, leaves oblong-ovate with entire to sinuate margins, cell walls with small trigones at leaf base and midleaf, increasing in size toward the leaf margins, and lobules distant to subimbricate with a rounded base, covering 1/3 to overlapping the stem. The new variety differs from the type variety by plants paroicous, leaf cells with trigones small or lacking, and absence of caducous leaves. A full description and illustration of the new taxa as well as comments on morphology, taxonomy, and distribution are provided.

Key words: *Radula* sp.nov.ined. *Radula fendleri* var. ined., Liverworts, Taxonomy.

Introduction

Radula Dumortier (1822: 112) is a monotypic genus that includes about 200 species worldwide, occurring from the Arctic to Antarctic regions with greatest diversity in the tropics and subtropics (Yamada 1979, 2003, Gradstein et al. 2001, Söderström et al. 2016). The members of the genus usually occur on bark, decaying wood, or living leaves, rarely on rock or soil, inhabiting diverse environments, from sea level to over 4000 m elevation (Gradstein et al. 2001, Devos et al. 2011a). Morphologically, the genus presents singular characteristics such as (1) *Radula*-type

branches, (2) incubous, lobulate leaves, (3) underleaves absent, (4) rhizoids in tufts on lobule surface, and (5) perianth tubular, dorsiventrally flattened (Schuster 1980b, Gradstein *et al.* 2001, Yamada 1979, Crandall-Stotler *et al.* 2009).

Several studies have dealt with the *Radula* species of Brazil. The first species lists were published by Yano (1984, 1989, 1995), totalling 39 species. Afterward, Yamada (2003) recognized 29 species in the country and Yano (2008) 34. Most recently, Costa & Peralta (2015) reported 26 species from Brazil.

In a taxonomic study of *Radula* in Brazil by the first author (unpublished data) 30 species were accepted so far. In the course of this study, a new species from Bahia and a new variety of *Radula fendleri* Gottsche (1984:146) from Rio de Janeiro were detected.

The aim of this paper is to describe these new taxa, with illustrations and comments on their morphology, taxonomic affinities, and distribution.

Taxonomic Treatment

Radula bahiensis F.R.Oliveira-da-Silva, Ilk.-Borg. & Gradst., *sp. nov.* (Fig. 1)

Dioicous. Plants irregularly pinnate. Leaves widely spreading, imbricate, oblong-ovate, margins entire to sinuate; cell walls thin, trigones small at leaf base and midleaf, increasing in size toward the leaf margins, cuticle smooth. Lobules distant to subimbricate, subquadrate, base rounded, covering 1/3 to overlapping the stem, apex rounded to obtuse, distal margin ± straight to rounded, keel straight to sinuate, spreading at angles of 30–40° with the stem, inflated along the keel.

Type:—BRAZIL. Bahia: Uruçuca, 6.2 Km N of town of Serra Grande, ca. 40 Km N of Ilhéus along coast, wet tropical forest with small stream in ravine, 14°26' S, 39°03' W, 200 m, 17 July 1991, Vital & Buck 20271 (holotype SP353920!, isotype MG!).

Dioicous. **Plants** 2000–3500 µm wide, green to olive-green in herbarium, irregularly pinnate branched. **Stems** in cross section with ca. 29 thick-walled epidermal cells surrounding ca. 47 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones small. **Leaves** widely spreading, imbricate, ± convex, oblong-ovate, 1000–1800 µm long, 600–1100 µm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin plane, entire to sinuate; marginal cells subquadrate, 12–20(–30) × 10–15 µm, median and basal cells isodiametric to elongate, 20–25(–

$30) \times 15\text{--}20 \mu\text{m}$, cell walls thin, trigones small at leaf base and midleaf, increasing in size toward the margins, cuticle smooth. **Lobules** distant to subimbricate, subquadrate, $700\text{--}900 \mu\text{m}$ long, $500\text{--}700 \mu\text{m}$ wide, ca. 1/2 of the lobe length, insertion line \pm straight, base plane, rounded, covering 1/3 to overlapping the stem, free margin plane, straight, apex rounded to obtuse, distal margin \pm straight to rounded, keel straight to sinuate-concave, spreading at angles of $30\text{--}40^\circ$ with the stem, lobule inflated along the keel. **Rhizoids** colorless, scanty. **Androecia** intercalary to terminal on long branches, 2–4 pairs of bracts, $1100\text{--}1400 \mu\text{m}$ wide; bracts distant to contiguous, ovate, $800\text{--}1000 \mu\text{m}$ long, $300\text{--}500 \mu\text{m}$ wide, apex rounded, margin plane, entire to sinuate, lobule distant to contiguous, ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex rounded, keel convex, inflated. **Gynoecia** terminal on long branches, with one subfloral innovation; bracts oblong-ovate, $1000\text{--}1300 \mu\text{m}$ long, $600\text{--}800 \mu\text{m}$ wide, apex rounded, margin plane, entire, lobule ovate, ca. 1/3 of lobe length, apex rounded. **Perianth** not seen. **Vegetative reproduction** by stem fragmentation and caducous branches.

Distribution and habitat:—This species is only known from the State of Bahia (Brazil), growing on tree trunks in Atlantic forest, at 50–200 m elevation. The examined specimens were collected in three municipalities of Bahia, located close to each other and near the ocean (Fig. 2).

Etymology:—The epithet of the new species refers to its known distribution.

Taxonomic notes:—*Radula bahiensis* is characterized by (1) plants irregularly pinnate; (2) leaf lobes widely spreading, imbricate, oblong-ovate, apex rounded to obtuse, margin entire to shallowly sinuate; (3) leaf cells with small trigones at leaf base and midleaf, increasing in size toward the leaf margins; (4) lobules distant to subimbricate, subquadrate, base rounded, covering 1/3 to overlapping the stem, apex rounded to obtuse, distal margin straight to rounded, keel straight to sinuate-concave, spreading at angles of $30\text{--}40^\circ$ with the stem, lobule inflated along the keel.

The specimens were identified as *R. kegelii* Stephani (1884: 152) (=*R. pallens* (Sw.) Montagne [1839: 71], fide Gradstein in press) in herbaria NY and SP. At first glance, the new species indeed resembles *R. pallens* by plants relatively robust (2 to 3 mm wide), leaf lobes widely spreading, and lobule keel straight to sinuate-concave. During the taxonomic study of *Radula* in Brazil, 108 specimens of *R. pallens* were compared with the isolectotype of *R. kegelii* (G00264270!) and confirmed for 15 states of Brazil, including Bahia. However, *R. bahiensis* and *R. pallens* are clearly different. Plants in *R. bahiensis* are never dichotomous, while vary from irregularly pinnate to dichotomous in *R. pallens*. Additionally, *R. bahiensis* presents leaves oblong-ovate with rounded to obtuse apex (suborbicular with broadly rounded apex in *R. pallens*); trigones small at base and midleaf increasing in size toward the margins (trigones usually lacking in *R. pallens*); lobules distant to subimbricate and large, $700\text{--}900 \times 500\text{--}700 \mu\text{m}$ (distant and small,

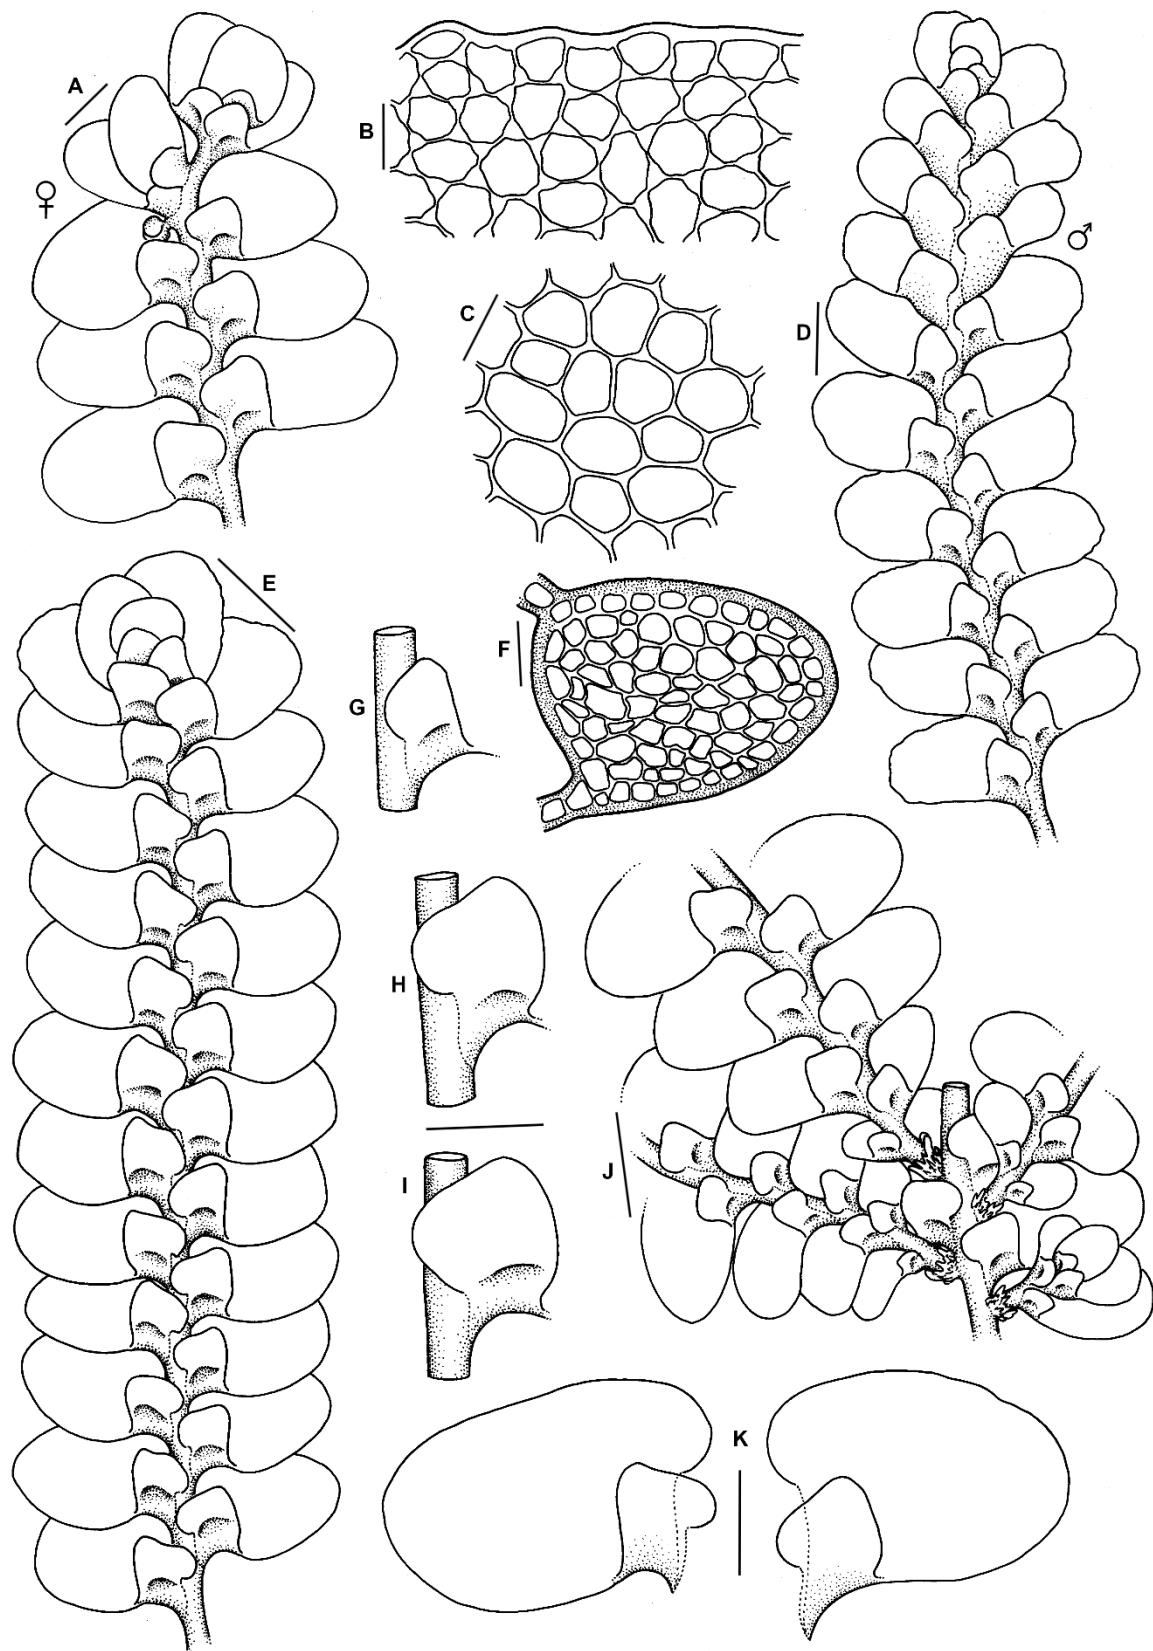

Figure 1. A-K. *Radula bahiensis*. A. Habit with gynoecia. B. Marginal leaf cells. C. Median leaf cells. D. Habit with androecia. E, J. Habit. F. Cross section of a stem. G-I. Lobules. K. Leaves. (A, C, G, H, I, K= 500 μm ; B, D= 25 μm ; F= 50 μm ; E, J= 1000 μm ; A, E from SP353920; D from NY1670325; B, C, F, G, H, I, J, K from SP373105).

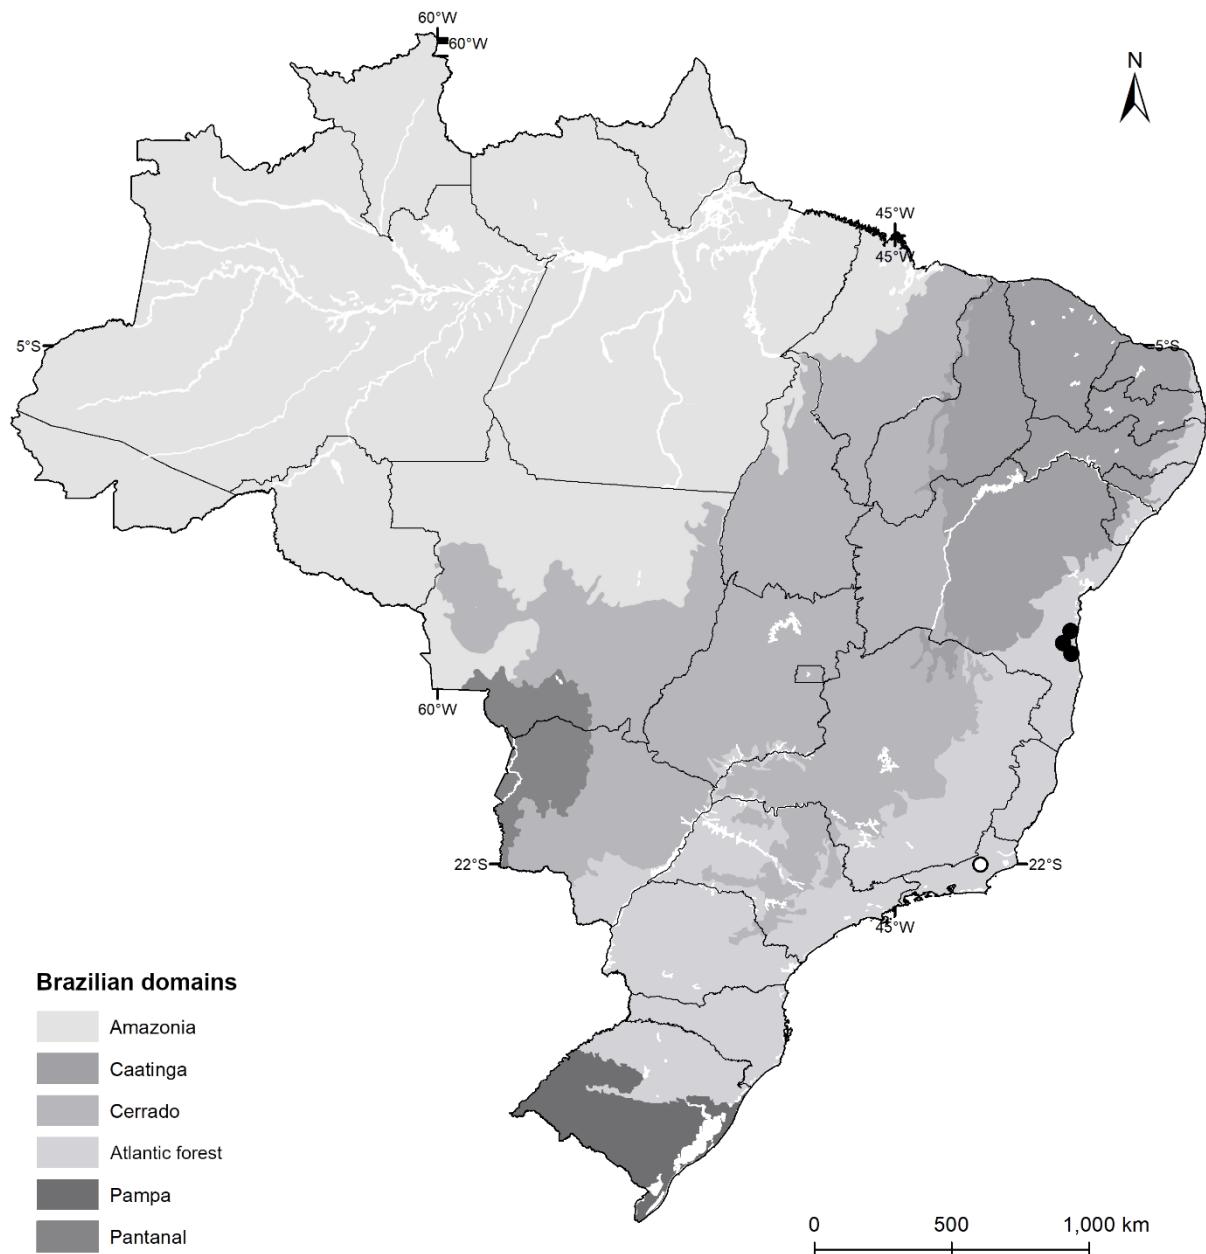

Figure 2. Distribution of *Radula bahiensis* (black dot) and *R. fendleri* var. *paroica* (white dot).

300–600 × 200–500 µm, in *R. pallens*); base covering 1/3 to overlapping the stem (usually covering 1/4–1/2 of stem in *R. pallens*).

By the size of the leaf cells and presence of trigones, *R. bahiensis* seems rather similar to the Andean *R. jamesonii* Taylor (1846: 375). However, *R. bahiensis* differs from the latter species mainly by leaves never falcate and lobule base covering 1/3 to overlapping the stem. In *R. jamesonii*, leaf lobes are usually falcate and lobule bases cover maximally 1/2 the stem width.

The specimens from herbarium SP (SP373105) presented intercalary branches at the base of lobules (*Lejeunea*-type), beside the typical *Radula*-type branches (Figure 1J). Crandall (1969)

named these “adventitious *Radula*-type” branches, reported them from *R. longituba* Stephani (in Herzog 1916: 87) (=*R. mammosa* Spruce [1890: 127]) (Crandall 1969, plate 19-21) and *Radula* sp. (plate 19), and mentioned that they were associated with decapitated shoots. The latter observation was also made in *R. bahiensis*.

Additional specimens (paratypes):—BRAZIL. Bahia: Una, Maruim, border of the fazendas Maruim and Dois de Julho, 33 km SW of Olivença on road from Olivença to Burarema, Southern Bahian wet forest, epiphytic on tree, in full shade, 28 April 1981, Boom et al. 811 (NY1670325!); Ilhéus, "área do CEPEC (Centro de Pesquisas do Cacau), km 22 da rodovia Ilhéus/Itabuna BR415, restinga, cipó grosso, restinga arenosa e muito sol," 14°47'20" S, 39°02'58" W, 50 m, 17 July 1991, Vital s.n. (SP373105!).

Radula fendleri* var. *paroica F.R.Oliveira-da-Silva, Ilk.-Borg. & Gradst., **var. nov.** (Fig. 3)

Differs from Radula fendleri var. fendleri by plants paroicous, trigones lacking or small, caducous leaves absent.

Type:—BRAZIL. Rio de Janeiro: Nova Friburgo, "Estrada para Teresópolis, sobre pau podre na capoeira," 6 May 1927, Vaughan Bandeira s.n. (holotype RB99454!).

Paroicous. **Plants** 1000–1800 µm wide, brown in herbarium, irregularly pinnate. **Stems** in cross section with ca. 16 thick-walled epidermal cells surrounding ca. 13 thick-walled medullary cells, epidermal and medullary cells of the same size, cell walls brownish, trigones large. **Leaves** widely spreading, imbricate, strongly convex, ovate to ± falcate-ovate, 600–800 µm long, 500–600 µm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin strongly recurved, entire; marginal cells subquadrate, 7–10 µm diam., median and basal cells isodiametric to elongate, 15–25 × 10–15 µm, cell walls thin, trigones lacking to small, cuticle minutely verrucose. **Lobules** distant, subrectangular, 300–500 µm long, 100–270 µm wide, ca. 1/2 the lobe-length, insertion line ± arched, base plane, rounded, covering 1/3(–1/2) of the stem, free margin plane, ± straight, apex rounded, rarely obtuse, distal margin ± straight, keel arched, spreading at angles of 45–60° with the stem, lobule strongly inflated along the keel. **Rhizoids** colorless, scanty. **Androecia** terminal or preceding a gynoecia on short branches, 1–3 pairs of bracts, 550–1000 µm wide; bracts distant to contiguous, ovate, 450–750 µm long, 200–400 µm wide, apex rounded, margin strongly recurved, entire, lobule imbricate, ovate, ca. 3/4 of lobe length, base rounded to obtuse, free margin ± straight, apex rounded to obtuse, keel straight or convex, inflated. **Gynoecia**

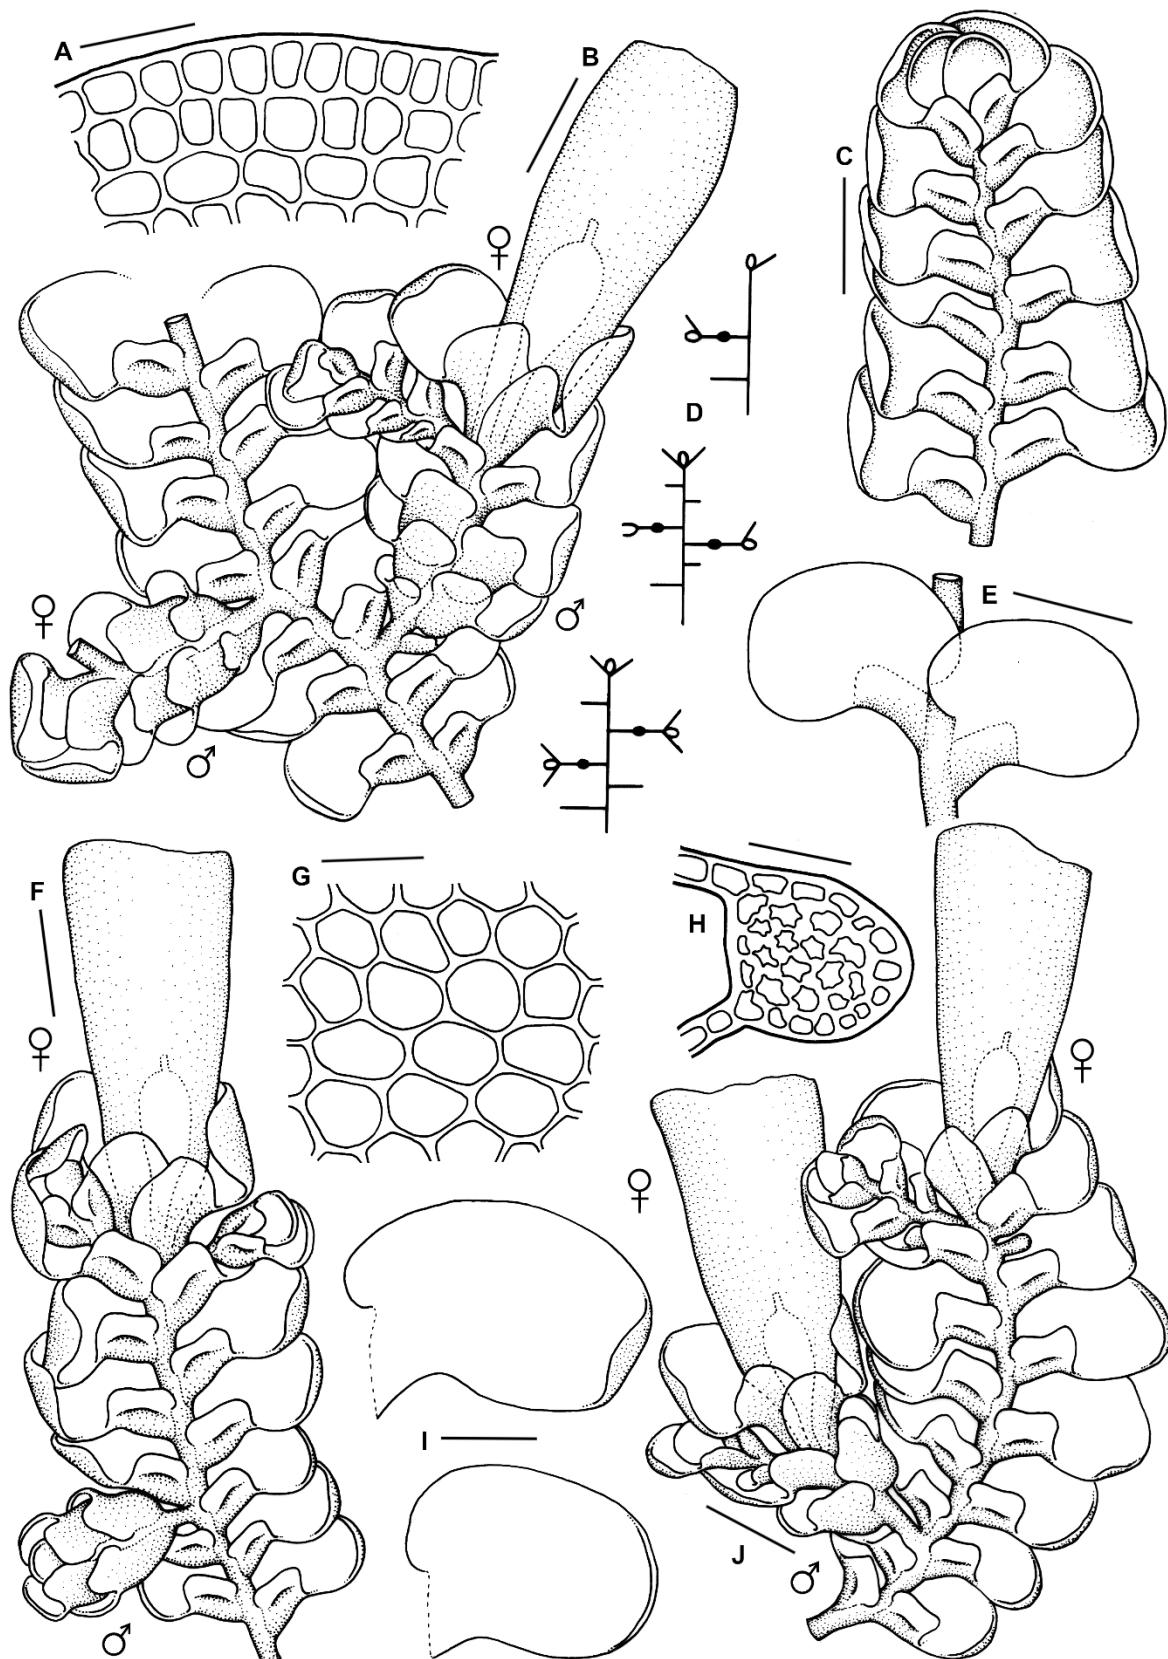

Figure 3. A-J. *Radula fendleri* var. *paroica*. A. Marginal leaf cells. B, C, F, J. Habit. D. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). E. Leaf, dorsal view. G. Median leaf cells. H. Cross section of a stem. I. Leaf lobes. (A, G= 25 μm ; B, C, E, F, J= 500 μm ; H= 50 μm ; I= 250 μm ; A-J from RB99454).

terminal on long branches, with 1-2 subfloral innovations; bracts ovate, 750–1000 µm long, 550–600 µm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex obtuse. **Perianth** subcylindrical, 1850–2200 µm long, 650–900 µm wide at apex, mouth entire to irregularly undulate. **Vegetative reproduction** not seen.

Distribution and habitat:— *Radula fendleri* var. *paroica* is known from Rio de Janeiro only, growing on decaying wood in humid Atlantic Forest.

Etymology:— The epithet of the new variety refers to its paroicous condition.

Taxonomic notes:— The new variety differs from the typical variety by plants paroicous (dioicous in var. *fendleri*), leaf cells with trigones small or lacking (trigones large in var. *fendleri*), and by the absence of caducous leaves (caducous leaves present in var. *fendleri*).

Due to its monoicous condition, the new variety may be confused with two monoicous species that occur in Brazil, *R. mexicana* Lindenberg & Gottsche (1863: 150) and *R. complanata* (L.) Dumortier (1831: 38). However, these two species differ from *R. fendleri* var. *paroica* by the subquadrate lobule with usually elongate apex. In addition, *R. mexicana* is usually autoicous and *R. complanata* produces small discoid gemmae on leaf margins.

Acknowledgment

The authors are grateful to Dr. Rafaella Forzza and Dr. Barbara Thiers for logistic support during the visit to the Herbaria RB and NY, respectively; to Dr. Denilson F. Peralta for the loan of *Radula* specimens from Herbarium SP; to the Museu Paraense Emílio Goeldi and the Programa de Pós-graduação em Ciências Biológicas - Botânica Tropical (UFRA/MPEG) for logistical support; to the National Council for Scientific and Technological Development (CNPq) for the Master's fellowship grant of the first author (process n°132059/2018-5), and for the productivity fellowship grant of the third author (process n°302374/2016-7); This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

CAPÍTULO II

On a new species of *Radula* Dumort. (Radulaceae, Machantiophyta) from mountain ranges in the Atlantic Forest, Brazil

Fúvio Rubens Oliveira-da-Silva¹, Anna Luiza Ilkiu-Borges²

¹Posgraduation Program in Biological Sciences – Tropical Botany (UFRA/MPEG), Museu Paraense Emílio Goeldi, Coordination of Botany, Av. Perimetral 1901, 66530-070 Belém, Brazil, ²Museu Paraense Emílio Goeldi, Coordination of Botany, Av. Perimetral 1901, 66530-070 Belém, Brazil.

Abstract: *Radula sp.nov.ined.2*, a species from mountain ranges in the Antlantic forest, is proposed here as new to science. The new species is characterized by plants occasionally epiphyllous, densely branched, leaf lobes imbricate, ovate, apex obtuse to subacute, cell walls thin, trigones small, lobules distant to contiguous, rarely imbricate, subquadrate, 1/2–2/5 the lobe length, base rounded to obtuse, covering 1/3 to overlapping the stem, keel conspicuously convex, strongly inflated at rhizoid area and along the keel, and rhizoid numerous. A complete description and illustration of the new taxa as well as comments on morphology, taxonomy, and distribution are provided.

Key words: Leafy liverworts; taxonomy; Neotropics; epiphyll.

Introduction

The Atlantic Forest extends from Rio Grande do Norte to Rio Grande do Sul states, from Northeastern to Southern Brazil, occurring in coastal and inland areas over mountain ranges and plateaus (Gradstein & Costa 2003, Silva & Casteleti 2005). This important phytogeographic domain harbors the highest number of bryophytes species (1337 species) and endemic taxa (242 spp.) (Gradstein & Costa 2003, Costa & Santos 2009, Costa & Peralta 2015). It is the third richest neotropical region in terms of liverworts diversity, behind only the Andes and Central America (Gradstein et al. 2001).

Radulaceae is the fifth largest family of liverworts in Brazil (Costa & Peralta 2015), presenting its greatest diversity in the Atlantic forest with one endemic species from Serra da Mantiqueira, in São Paulo state (*Radula brasiliaca* K.Yamada). *Radula* Dumort. is a monotypic genus that presents singular characteristics distinguishing it from other leafy liverworts such as (1) *Radula*-type branches (2) incubous, lobulate leaves, (3) underleaves absent, (4) rhizoids in tufts on lobule surface, and (5) perianth tubular, dorsiventrally flattened (Schuster 1980, Gradstein et al. 2001, Yamada 1979, Crandall-Stotler et al. 2009).

During a taxonomic study of *Radula* in Brazil, a new species from the ranges *Serra do Mar* and *Serra Murumbi* in the Atlantic forest was detected. The new species deviated from other *Radula* species in Brazil by leaf apex obtuse to subacute. Further diagnostic characters can clearly separate the new taxon in the genus.

The aim of this paper is to describe the new *Radula* species with illustrations and comments on its morphology, taxonomic affinities, and distribution.

Taxonomic Treatment

***Radula yamadae* F.R.Oliveira-da-Silva & Ilk.-Borg., sp. nov. (Fig. 1)**

Dioicous. Plants occasionally epiphyllous, densely branched. Stem robust, in cross section with ca. 30 thick-walled epidermal cells surrounding ca. 60 thin-walled medullary cells. Leaves widely spreading, imbricate, ovate, apex obtuse to subacute; cell walls thin, trigones small. Lobules distant to contiguous, rarely imbricate, subquadrate, ca. 1/2 the lobe length, base rounded to obtuse, covering 1/3 to overlapping the stem, keel conspicuously convex, spreading at angles of 60° with the stem, strongly inflated at rhizoid area and along the keel. Rhizoid numerous.

Type: Brazil, São Paulo, São Luiz do Piraitinga, Parque Estadual da Serra do Mar, Núcleo Santa Virginia, trilha do Corcovado, Mata Atlântica, sobre folhas, 23°24'07" S, 45°11'33" W, 981 m, 11 June 2013, *Peralta & Carmo* 14155 (holotype SP438627!).

Dioicous. **Plants** 1000–2000(–2500) µm wide, yellowish-green to pale green in herbarium, densely branched. **Stems** robust, in cross section with ca. 30 thick-walled epidermal cells surrounding ca. 60 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls colorless, trigones lacking. **Leaves** widely spreading, imbricate, slightly convex, ovate, 700–1200 µm long, 500–800 µm wide, dorsal base rounded, overlapping the stem, apex obtuse to subacute, margin plane, entire; marginal cells subquadrate to isodiametric, 12–17 × 10–12 µm, median and basal cells isodiametric to elongate, 12–22 × 10–15 µm, cell walls thin, trigones small to lacking, cuticle smooth. **Lobules** distant to contiguous, rarely imbricate, subquadrate, 300–600 µm long, 250–500 µm wide, 1/2–2/5 the lobe length, insertion line arched, base plane, rounded to obtuse, covering 1/3 to overlapping the stem, free margin plane, straight to sinuate, apex rounded to obtuse, distal margin ± straight, keel conspicuously convex, spreading at angles of 60° with the stem, lobules strongly inflated at rhizoid area and along the keel. **Rhizoids** colorless to brown, numerous. **Androecia**, **Gynoecia**, and **Vegetative reproduction** not seen.

Additional Specimens (Paratype): Paraná, Morretes, Parque Estadual do Marumbi, trilha vermelha, caminho para a ponta do tigre, Mata Atlântica com afloramentos rochosos, sobre rocha, 25°26'55" S, 48°54'54" W, 1200 m, 22 July 2014, *Peralta et al.* 15877 (SP452299!, MG!).

Distribution and Ecology

The new species is thus far known only from two collections from Paraná (Serra Murumbi) and São Paulo (Serra do Mar), growing on leaves and rocks, respectively, at 981–1200 m elevation. The two mountain ranges are located in the Atlantic Forest domain, presenting both type of forests: Dense Mountain Ombrophylous Forest and Dense High Mountain Ombrophylous Forest (Carmo et al. 2016, Santos 2016).

Etymology

The epithet of the new species is dedicated to Dr. Kohsaku Yamada, a renowned expert in *Radula*, who most published papers on the genus worldwide, especially contributing to the knowledge of *Radula* in the Neotropics.

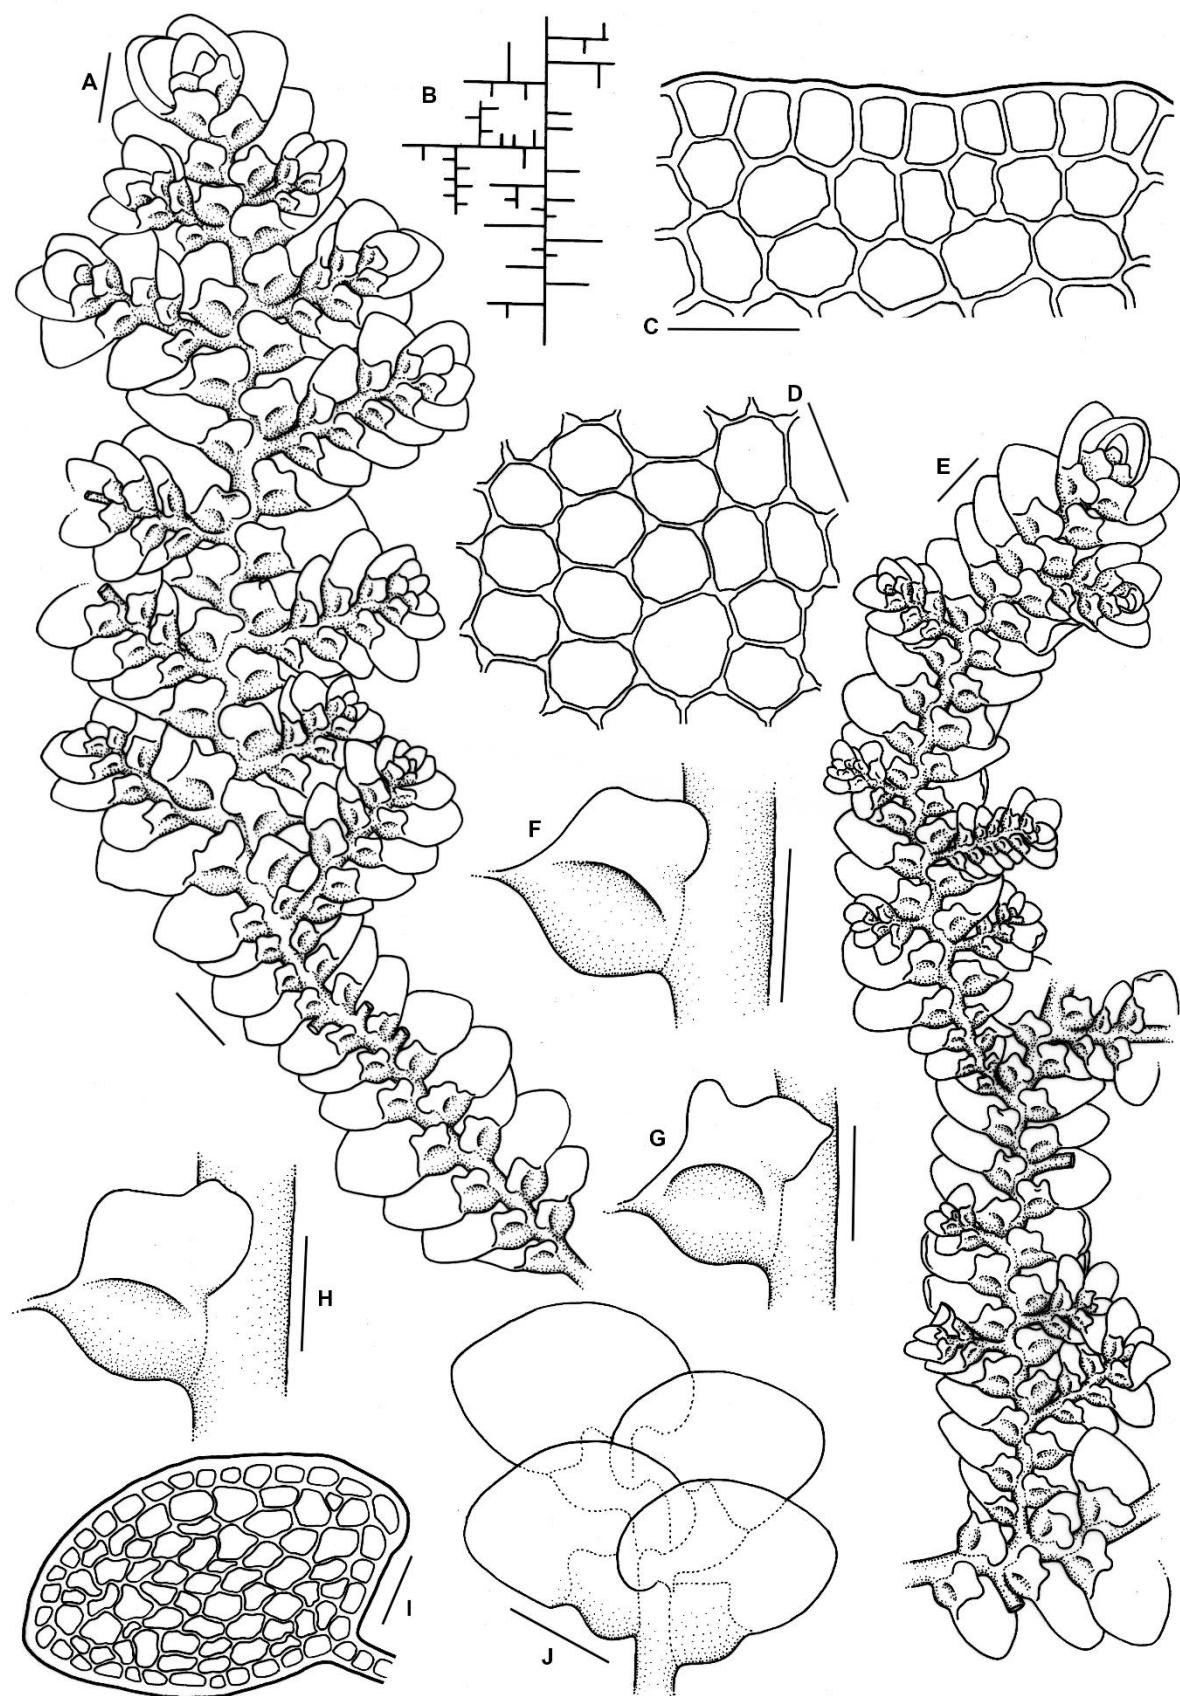

Figure 1. A-J. *Radula* sp.nov.ined.2. A, E. Habit. B. Cladograph of plants. C. Marginal leaf cells. D. Median leaf cells. F-H. Lobule. I. Cross section of a stem. J. Habit, dorsal view (A, E, J= 500 μm ; C, D= 25 μm ; F-H= 250 μm ; I= 50 μm ; A-J from the SP438627).

Discussion

Radula yamadae is characterized by (1) plants occasionally epiphyllous, densely branched; (2) stem robust, in cross section with ca. 30 thick-walled epidermal cells surrounding ca. 60 thin-walled medullary cells, cell walls colorless; (3) leaf lobes imbricate, ovate, apex obtuse to subacute; (4) cell walls thin, trigones small; (5) lobules distant to contiguous, rarely imbricate, subquadrate, 1/2–2/5 the lobe length, base rounded to obtuse, covering 1/3 to overlapping the stem, keel conspicuously convex, strongly inflated at rhizoid area and along the keel; (6) rhizoid numerous.

The tendency of growing on leaves has been used as a character for separating *Radula* species (e.g. Castle 1936, Yamada 2003, Promma & Chantanaorrapint 2015). However, many epiphyllous species, such as *Radula flaccida* Lindenb. & Gottsche and *R. stenocalyx* Mont., are not limited to growth on living leaves but are occasionally found growing on tree trunks, decaying wood or rocks. Although the colonization of living leaves is not a restriction, it is still a good character for distinguishing some species, including *R. yamadae*.

The new species resembles *Radula longiloba* K.Yamada (isotype NICH400981!) by dioicous and occasionally epiphyllous plants, leaf apex obtuse to subacute, and leaf cell walls thin, with small trigones or trigones lacking. *Radula yamadae*, however, clearly differs from *R. longiloba* by robust stems with ca. 90 cells (epidermal plus medullary cells), leaves ovate and widely spreading, dorsal leaf base rounded overlapping the stem, lobules distant to contiguous, rarely imbricate, 1/2–2/5 the lobe length, lobule base covering 1/3 to overlapping the stem, and lobule keel conspicuously convex. In *R. longiloba*, stems are much thinner (ca. 30 cells); leaves are oblong and falcate; dorsal leaf bases are rounded and cover the stem (never overlap); lobule are distant, 1/3–1/4 the leaf length, which base covers up to 1/3 the stem and keel is straight to hardly convex.

The lobule in the new species is highly variable on a plant, while in *Radula longiloba* no significant variation was observed (see Yamada 1983, Fig. 2).

Because of epiphyllous habit, absence of gemma, and for presenting convex keel with numerous and well-developed rhizoid-bundles, *R. yamadae* could be misinterpreted as *R. mammosa* Spruce (isotype NY01021130!, G00265038!). However, the differences between the new species and *R. mammosa* are the oblong leaves obtuse to subacute apex, dorsal base overlapping the stem and lobule base rounded to obtuse, covering 1/3 to overlapping the stem as well. In *R. mammosa*, leaf lobes are ovate to falcate-ovate with rounded apex, dorsal leaf base do not overlap the stem and lobule base are straight and do not cover the stem (Yamada 1993).

Acknowledgements

The authors are grateful to Dr. Denilson F. Peralta for the loan of *Radula* specimens from Herbarium SP; to the Museu Paraense Emílio Goeldi and the Posgraduation Program in Biological Sciences – Tropical Botany (UFRA/MPEG) for logistical support; to the *National Council for Scientific and Technological Development* (CNPq) for the Master's fellowship grant of the first author (process n°132059/2018-5) and for the productivity fellowship grant of the second author (process n°302374/2016-7); This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

Abstract: A taxonomic study of the liverwort genus *Radula* in Brazil based on morphological characters and on examination of types and over 1000 additional collections, leads to the recognition of 31 species and two varieties. A key to all species as well as descriptions, illustrations and comments on recognition, distribution and habitat of the recognized species are provided. One new species, *R. renneri*, is described and illustrated. *Radula longiloba*, *R. punctata* and *R. xalapensis* are new records for Brazil whereas the occurrence of *R. pseudostachya* and *R. subinflata* in Brazil is confirmed. *Radula elliotii*, *R. varilobula* and *R. wrightii* are excluded from the country and *R. marginata*, *R. microloba* and *R. saccatiloba* are doubtful records. Several new lectotypifications [for *R. flaccida*, *R. epiphylla* (=*R. flaccida*), *R. quadrata*, *R. stenocalyx*, *R. tectiloba* and *R. tenera*] and one new neotypification (for *R. yanoella*) are proposed. *Radula obovata* is proposed as a new synonym of *R. pallens*.

Key words: bryophytes; hepatic; liverworts; morphology; Neotropics; taxonomy; tropical biodiversity.

Introduction

Radula Dumort. is a large genus of leafy liverworts with about 200 species worldwide, most of them distributed in tropical and subtropical regions (Yamada 1979, 2003, Gradstein et al. 2001, Devos et al. 2011b, Patiño et al. 2017). The species occur from sea level to about 4000 m elevation and usually grow on bark, decaying wood, rock or living leaves, occasionally on soil (Gradstein et al. 2001).

Dumortier (1822) introduced the genus *Radula* based on eight species, including *Jungermannia complanata* L. [= *Radula complanata* (L.) Dumort.], which was conserved as the type of *Radula* (Grolle 1983). The genus is characterized by (1) terminal, *Radula*-type branches (originating from a stem epidermal cell and therefore associated with an unmodified leaf), (2) incubous, lobulate leaves, (3) underleaves absent, (4) rhizoids in tufts on lobule surface, and (5) perianth tubular, dorsiventrally flattened (Schuster 1980, Yamada 1979, 2003, Gradstein et al. 2001, Crandall-Stotler et al. 2009). *Radula* is well resolved in its own family and suborder, Radulaceae Müll.Frib. and Radulineae R.M.Schust., respectively (Crandall-Stotler et al. 2009). Based on morphological and molecular data, Devos et al. (2011a) subdivided the genus into seven subgenera: subg. *Amentuloradula* Devos et al., subg. *Dactyloradula* Devos et al., subg. *Cladoradula* Spruce, subg. *Metaradula* R.M.Schust., subg. *Odontoradula* K.Yamada, subg. *Radula*, and subg. *Volutoradula* Devos et al. The latter five subgenera occur in Brazil.

The genus *Radula* was first recorded from Brazil by Raddi (1823), who reported *R. complanata* and *R. pallens* (Sw.) Nees & Mont. from Rio de Janeiro State. Costa (2009), however, found that the record of *R. complanata* belonged to *R. voluta* Taylor while the collection of *R. pallens* was missing in the Raddi herbarium. Subsequently, many additional *Radula* species have been recorded from Brazil (e.g., Nees 1833, Spruce 1885, Stephani 1910, Dusén 1903, Castle 1959, 1962, 1963, 1964, Schiffner & Arnell 1964, Oliveira 1973). The latter author presented a key to the species of Rio Grande do Sul together with brief morphological descriptions and illustrations. Yano (1984, 1989, 1995) recorded 39 species of *Radula* in a checklist of liverworts and hornworts of Brazil, but only 27 were accepted by Yamada (2003) in a first taxonomic account of the genus for the country, with a key, comments on habitat and distribution, and illustrations of the species. In the latest version of the Brazil checklist, Yano (2008) listed 34 species for the country, including seven species excluded by Yamada (2003). Costa & Peralta (2015) considered Radulaceae the sixth most diverse liverwort family of Brazil, with 26 species including one endemic, *Radula brasiliaca* K.Yamada. Recently, we described two new species and one new variety from Brazil, *Radula yamadae* Oliveira-da-Silva & Ilkiu-Borges (Oliveira-da-Silva & Ilkiu-

Borges 2020), *R. bahiensis* Oliveira-da-Silva et al. and *R. fendleri* Steph. var. *paroica* Oliveira-da-Silva et al. (Oliveira-da-Silva et al. 2020).

Information on the Brazilian species of *Radula* is highly scattered across the literature. Besides the brief account of Yamada (2003), which lacks species descriptions, there is no comprehensive taxonomic treatment of the genus for the country. A taxonomic revision of the species of *Radula* of the world was carried out by Castle (1937, 1939, 1950, 1959a, 1959b, 1962, 1963, 1964, 1965, 1966, 1969) and useful accounts of selected Neotropical species were published by Yamada (e.g., 1980, 1981, 1982, 1987, 1991, 1993a). In addition, brief treatments for Neotropical areas are available for Cuba (Yamada 1988), the Galápagos Islands (Yamada & Gradstein 1991) and French Guiana (Gradstein & Ilkiu-Borges 2009). Many Neotropical species, however, remain insufficiently known (Renner 2016).

The aim of this paper is to present a comprehensive taxonomic treatment of *Radula* in Brazil, based on study of type specimens and additional herbarium collections.

Materials and methods

Type specimens and over 1000 additional collections from 16 herbaria (ALCB, BM, G, GOET, HBRA, ICN, INPA, JE, MG, NICH, NY, PC, RB, S, SP, UFP) were examined. Leaf lobe and lobule, as well as details of the lobule, were measured as shown in Fig. 1. For taxonomic and geographical information on *Radula* species the main sources consulted were Castle (1937, 1939, 1950, 1959a, 1959b, 1962, 1963, 1964, 1965, 1966, 1969), Yamada (1979, 1980, 1981, 1982, 1983, 1987, 1990, 1991, 1993a, 1993b, 2003), Schuster (1980), Reiner-Drehwald (1994), Gradstein & Ilkiu-Borges (2009), Gradstein (in press), Tropicos (<http://www.tropicos.org/>), JSTOR Plant Sciences (<http://plants.jstor.org>) data on *Radula* in Brazil (<http://floradobrasil.jbrj.gov.br/>; <http://splink.cria.org.br/>) and biodiversity heritage library (<http://biodiversitylibrary.org>). Distribution maps were produced at the Space Analysis Laboratory (UAS/MPEG).

Results and discussion

In this study, 31 species and two varieties of *Radula* are recognized for Brazil. *Radula longiloba* K.Yamada, *R. punctata* Steph. and *R. xalapensis* Nees & Mont. are new to Brazil, while the occurrence of *R. pseudostachya* Spruce and *R. subinflata* Lindenb. & Gottsche in Brazil is confirmed. The latter two species had been reported from Brazil by Yano (1984), Yamada (1980) and Costa (1992), but were not included in recent lists (e.g., Yamada 2003, BFG 2018). *Radula*

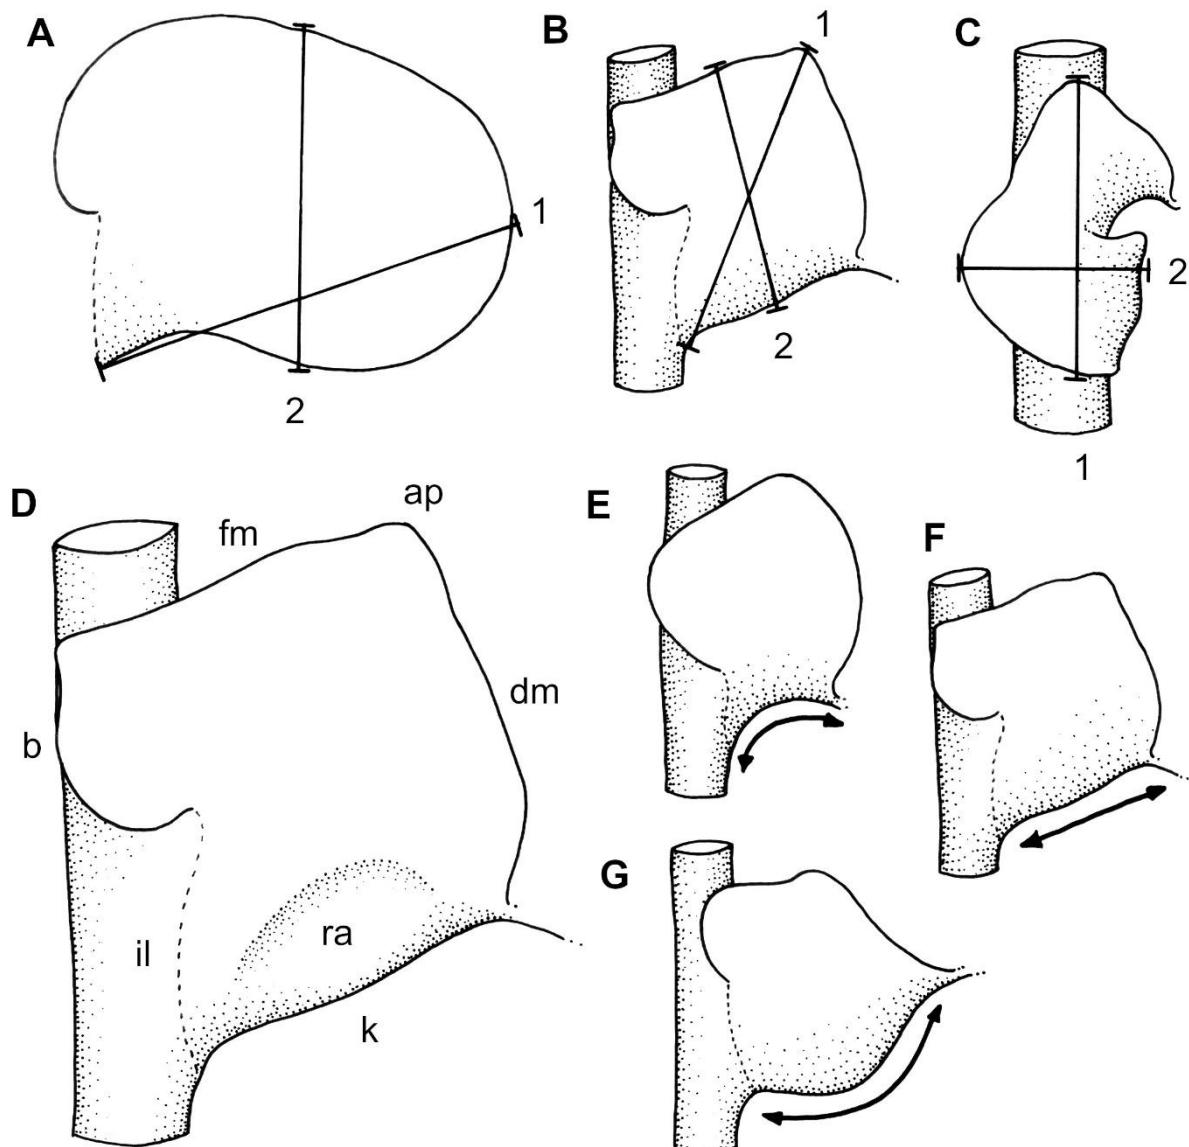

Figure 1. A-G. Schemes for measurement of leaf lobes and lobules and morphology of a lobule in *Radula*. A. Scheme for measurement of leaf lobes (1= long; 2= wide). B-C. Schemes for measurement of lobules (1= long; 2= wide). D. Lobule morphology (il= insertion line; b= base; fm= free margin; ap= apex; dm= distal margin; k= keel; ra= rhizoid area). E. Lobule with concave keel. F. Lobule with straight keel. G. Lobule with convex keel.

wrightii Castle, *R. varilobula* Castle and *R. elliottii* Castle are excluded from the Brazilian flora, and *R. marginata* Gottsche, Lindenb. & Nees, *R. microloba* Gottsche and *R. saccatiloba* Steph. are listed as doubtful records. *Radula wrightii* was firstly cited for Brazil (Minas Gerais) by confirmed. The latter two species had been reported from Brazil by Yano (1984), Yamada (1980) and Costa (1992), but were not included in recent lists (e.g., Yamada 2003, BFG 2018). *Radula wrightii* Castle, *R. varilobula* Castle and *R. elliottii* Castle are excluded from the Brazilian

flora, and *R. marginata* Gottsche, Lindenb. & Nees, *R. microloba* Gottsche and *R. saccatiloba* Steph. are listed as doubtful records. *Radula wrightii* was firstly cited for Brazil (Minas Gerais) by Yano (1984) with erroneous reference to Ångström (1876); the latter author did not mention the species (which had in fact not yet been described in 1876). Further Brazilian records of *R. wrightii* could not be confirmed in this study, therefore the species is excluded from the Brazilian list. The Brazilian specimens of *R. varilobula* and *R. elliotii* proved to be misidentifications and belong to *R. schaefer-verwimpii* K.Yamada and *R. angulata* Steph., respectively. The first record for Brazil of *R. microloba* from Rio Grande do Sul (Lindman 1906) and of *R. saccatiloba* from Rio de Janeiro (Dusén 1903) were not found in herbaria. *Radula marginata*, firstly reported from Rio de Janeiro (Oliveira e Silva & Feitosa 1997) were not examined and it is probably a misidentification (Reiner-Drehwald 1994, Yamada 2003). Since all other Brazilian collections of these three species proved to be misidentified, the occurrence of *R. marginata*, *R. microloba* and *R. saccatiloba* in Brazil is considered doubtful.

Concerning the worldwide distribution of Brazilian *Radula*, 13 species are widespread in tropical America, nine occur in tropical America and extend to subtropical and/or temperate regions of the continent, four species and one variety are endemic to Brazil, two are pantropical, one species is pantropical and occurs in northwestern Europe, one is Afro-American, and one occurs in tropical America and Macaronesia.

Widespread in tropical America: *Radula angulata*, *R. cubensis*, *R. fendleri* var. *fendleri*, *R. gottscheana*, *R. longiloba*, *R. mammosa*, *R. pallens*, *R. pocsii*, *R. pseudostachya*, *R. recubans*, *R. schaefer-verwimpii*, *R. tenera*, *R. yanoella*.

Tropical America and subtropical and/or temperate regions of the continent: *Radula decora*, *R. ligula*, *R. mexicana*, *R. punctata*, *R. quadrata*, *R. sinuata*, *R. subinflata*, *R. tectiloba*, *R. xalapensis*.

Endemic to Brazil: *Radula bahiensis*, *R. brasiliaca*, *R. fendleri* var. *paroica*, *R. renneri*, *R. yamadae*.

Pantropical: *Radula javanica*, *R. stenocalyx*.

Pantropical and NW Europe: *Radula voluta*.

Afro-American: *Radula flaccida*.

Tropical America and Macaronesia: *Radula nudicaulis*.

Within Brazil, the Atlantic Forest region and Amazonia harbor the highest number of species. Few species occur in the Cerrado, Pampa and Caatinga domains, and no *Radula* species

was recorded in Pantanal (Fig. 2). *Radula* species in Brazil occur from sea level to 2400 m elevation, growing on tree trunks, decaying wood and rock, occasionally on living leaves and soil. Six species (*R. flaccida*, *R. javanica*, *R. longiloba*, *R. stenocalyx*, *R. yamadae*, *R. yanoella*) occur on living leaves and four species (*R. convexa*, *R. javanica*, *R. fendleri*, *R. schaefer-verwimpii*) on soil. The species prevail in humid, shaded places such as the understory of old-growth primary forests. Secondary forests harbor a relatively poor *Radula* flora.

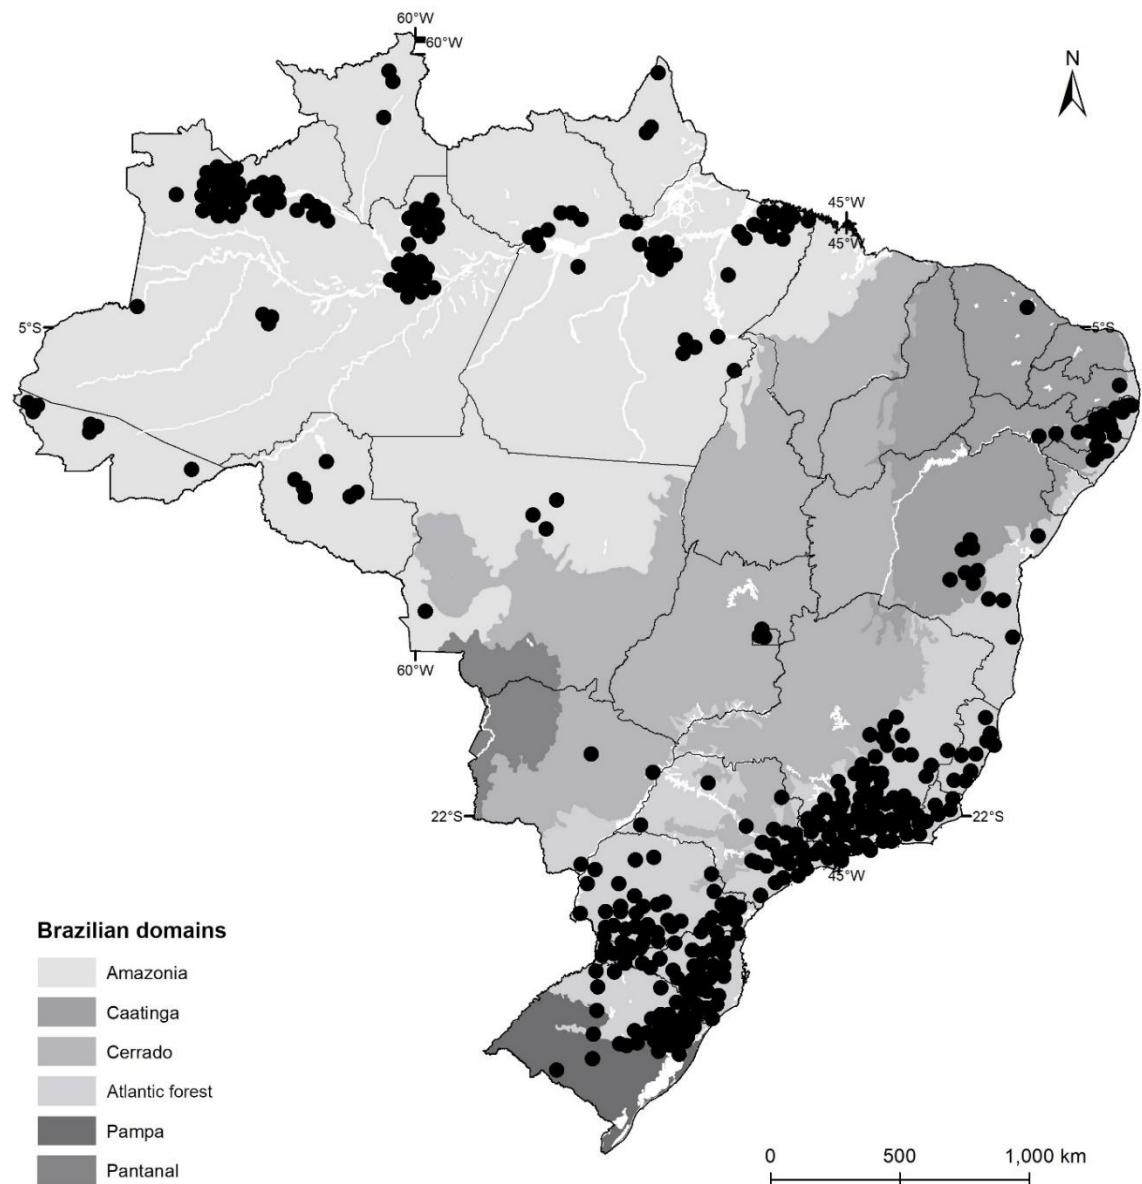

Figure 2. Distribution of *Radula* species in Brazil and the respective Brazilian domains of occurrence.

Taxonomic treatment

Radula Dumort., Comment. Bot. 112. 1822.

TYPE: *Jungermannia complanata* L. [=*Radula complanata* (L.) Dumort.] (lectotype: OXF, designated by Grolle 1969).

Dioicous, rarely monoicous. PLANTS 0.8–3.5(–4) mm wide, green to yellowish-brown, brown in herbarium, rarely reddish-brown, regularly or irregularly (bi)pinnate to dichotomous branched. BRANCHES *Radula*-type, rarely *Lejeunea*-type. THALLUS absent, rarely present (*R. yanoella*). STEMS in cross section with 10–140 thin to thick-walled epidermal cells surrounding 5–200 thin to thick-walled medullary cells, rarely with a subepidermis (together with the epidermis forming a 2–4-layered, brownish cortex), medullary cells larger than epidermal cells or of the same size, epidermal and medullary cell walls colorless, yellowish or brown, trigones present or lacking, small to large when present. LEAVES incubous, divided into a large dorsal lobe and a smaller ventral lobe (=lobule), dorsal lobe obliquely to widely spreading, sometimes squarrose, distant to imbricate, plane to strongly concave, orbicular to oblong-ovate, sometimes falcate, 0.4–1.8 mm long, 0.3–1.7 mm wide, dorsal base rounded, overlapping the stem or not, apex rounded to subacute, margin plane to strongly recurved, entire to crenulate; marginal cells subquadrate to isodiametric, rarely rounded, 5–25 × 5–20 µm, median cells isodiametric to elongate, 12–25(–38) × (8–)10–25 µm, basal cells isodiametric to elongate, 12–35(–40) × (8–)10–30 µm, cell walls thin to evenly thickened, trigones small to large, sometimes increasing in size towards the margins, cuticle smooth, rarely finely papillose. LOBULES obliquely to widely spreading, distant to imbricate, quadrate to rectangular, orbicular to oblong, triangular-ovate to triangular-oblong or ligulate to folded-lunular, 0.14–1.2 mm long, 0.1–1 mm wide, 1/3–1/2 the lobe length, inflated at the rhizoid area, along the keel or fully inflated, insertion line long to short, straight, arched, circinate or inverted J-shaped, base plane to recurved, rounded to angulate, sometimes straight, occasionally auriculate, overlapping the stem or not, free margin plane to strongly recurved, straight to rounded, sometimes sinuate, apex plane to recurved or incurved, rounded to subacute, sometimes extended, distal margin straight to rounded, sometimes sinuate; keel straight to concave or convex, spreading at angles of 25–80° with the stem. RHIZOID in a fascicle from the lobules, colorless to brown, scanty to numerous, occasionally produced on a pronounced mammiliform swelling. ANDROECIA terminal or intercalary on short to long branches, sometimes preceding the gynoecia (in paroicous plants), with 1–20 pairs of bracts, 0.3–1.7 mm wide; bracts imbricate, ovate, 0.25–1.2 mm long, 0.2–1 mm wide, apex rounded to obtuse, margin plane to recurved, entire, lobule hypostatic, imbricate, ovate to oblong, 1/2–3/4 of lobe length, base rounded to angulate, free margin straight to sinuate or recurved, apex rounded to subacute, keel convex,

inflated. GYNOECIA on short to long branches, without or with 1–2 innovations, the innovations rarely rudimentary; bracts ovate to oblong-ovate, 0.45–1.7 mm long, 0.2–0.8 mm wide, apex rounded to obtuse, margin plane to recurved, entire, lobule usually oblong, rarely ovate, 1/3–1/2 of lobe length, apex rounded to obtuse. PERIANTHS campanulate to subcylindrical or trumpet-shaped, 1.4–4 mm long, 0.37–1.7 mm wide at apex, mouth entire to irregularly crenulate-undulate. VEGETATIVE REPRODUCTION by caducous leaf lobes, fragmentation of leaf lobes, fragmentation of main branches, caducous *Lejeunea*-type branches, regenerants, and by discoid gemmae (30–450 µm in diam.) produced on leaf margins, rarely on the perianth mouth or on (male or female) bracts.

Key to the species of *Radula* in Brazil

1. Plants growing on living leaves..... 2
1. Plants not growing on living leaves..... 8
2. Plants with persistent thallus (=persistent protonema) with short leafy shoots sprouting from thallus margins *R. yanoella*
2. Plants without a persistent thallus 3
3. Discoid gemmae produced on leaf margins 4
3. Gemmae lacking 5
4. Gemmae large (350–450 µm in diam.), base of gemmae deeply cordate-auriculate. Lobule apex extended towards an obtuse tip *R. flaccida*
4. Gemmae smaller (40–200 µm in diam.), base of gemmae not cordate-auriculate. Lobule apex rounded *R. stenocalyx*
5. Leaf lobes caducous. Keel straight. Rhizoid area inflated but not prominently projecting outwards *R. javanica*
5. Leaf lobes not caducous. Keel strongly convex. Rhizoid area strongly inflated, prominently projecting outwards..... 6
6. Leaf apex rounded *R. mammosa*
6. Leaf apex obtuse to subacute 7
7. Lobules usually 1/3–1/4 the leaf length. Lobule base covering up to 1/3 the stem, keel straight (rarely slightly convex) *R. longiloba*
7. Lobules usually 1/2–2/5 the leaf length. Lobule base covering 1/3 to fully overlapping the stem, keel strongly convex..... *R. yamadae*
8. Discoid gemmae produced on leaf margins 9
8. Gemmae lacking 13

9. Plants 1–1.5 mm wide. Lobule base covering up to 1/2 the stem	10
9. Plants 1.6–2.8 mm wide. Lobule base covering 1/2 to fully overlapping the stem.....	11
10. Plants without caducous leaves	4
10. Plants with caducous leaves	22
11. Lobules imbricate, base usually fully overlapping the stem	<i>R. quadrata</i>
11. Lobules distant to subimbricate, base usually covering up to 2/3 the stem.....	12
12. Lobules distant. Lobule apex frequently somewhat extended, obtuse. Monoicous (paroicous) .	
.....	<i>R. renneri</i>
12. Lobules distant to subimbricate. Lobule apex not extended, rounded, rarely obtuse. Dioicous	
.....	<i>R. tectiloba</i>
13. Leaf lobes apex obtuse to subacute	7
13. Leaf lobes apex rounded.....	14
14. Lobule ligulate. Leaf lobes bordered by 3–4 rows of quadrate thick-walled cells.....	<i>R. ligula</i>
14. Lobule not ligulate. Leaf lobes not bordered.....	15
15. Lobule folded and lunular.....	<i>R. tenera</i>
15. Lobule not folded and lunular	16
16. Lobule base auriculate	17
16. Lobule base not auriculate	20
17. Lobule base rounded to slightly auriculate, insertion line inverted J-shaped. Plants regularly pinnate.....	<i>R. punctata</i>
17. Lobule base shortly to strongly auriculate, insertion line circinate. Plants irregularly pinnate ..	
.....	18
18. Auriculate base extending downwards beyond the keel. Keel short, 1/5–1/4 of leaf length.....	
.....	<i>R. gottscheana</i>
18. Auriculate base not extending downwards beyond the keel. Keel longer, 1/3–1/2 of leaf length ..	
.....	19
19. Lobule with strongly auriculate base, the base extending across and well beyond the stem and circinately coiled. Leaf cells with trigones small at leaf base increasing in size towards the margins, becoming bulging.....	<i>R. voluta</i>
19. Lobule with slightly auriculate base, the base not extending beyond the stem and not circinately coiled. Leaf cells without trigones	<i>R. sinuata</i>
20. Plants with caducous leaves	21
20. Plants without caducous leaves	28
21. Plants 0.6–1.4 mm wide. Keel strongly convex	22

21. Plants 1–4 mm wide. Keel straight to slightly convex 23
 22. Free margin of the lobules strongly recurved *R. brasiliaca*
 22. Free margin of the lobules plane *R. schaefer-verwimpii*
 23. Leaf lobes strongly recurved. Cells with trigones large, cuticle verruculose 24
 23. Leaf lobes plane. Cells without or with trigones small, sometimes increasing in size from leaf base towards the margins, cuticle smooth 25
 24. Lobules distant, subrectangular (longer than wide). Lobule base covering up to 1/3 the stem *R. fendleri*
 24. Lobules contiguous to subimbricate, usually subquadrate. Lobule base covering 1/2 to fully overlapping the stem *R. pseudostachya*
 25. Lobule base usually covering 1/2 the stem *R. javanica*
 25. Lobule base usually covering 3/4 to fully overlapping the stem 26
 26. Plants 2.5–4 mm wide. Leaves distant to contiguous *R. xalapensis*
 26. Plants 1–1.8 mm wide. Leaves subimbricate to imbricate 27
 27. Leaf lobes ovate, margin entire. Cells with trigones small at leaf base increasing in size towards the margins. Keel spreading at angles of 60–70° with the stem *R. angulata*
 27. Leaf lobes ovate to falcate-ovate (strongly falcate on branches), margin entire to weakly undulate. Cells without trigones. Keel spreading at angles of 40–50° with the stem *R. cubensis*
 28. Lobule with conspicuously extended, subacute apex 29
 28. Lobule without conspicuously extended, subacute apex 30
 29. Lobule base rounded to angulate, covering 3/4 to fully overlapping the stem. Leaf cells with trigones small at leaf base increasing in size towards the margins. Dioicous *R. angulata*
 29. Lobule base rounded, covering up to 1/2 the stem. Leaf cells with trigones small or lacking. Monoicous *R. mexicana*
 30. Leaf lobes strongly convex 31
 30. Leaf lobes plane to slightly convex 32
 31. Lobules inflated at rhizoid area only. Leaf cells dorsally smooth *R. decora*
 31. Lobules inflated along the keel, flattened above. Leaf cells dorsally mammillose *R. subinflata*
 32. Lobules subrectangular (longer than wide). Monoicous (paroicous) *R. fendleri* var. *paroica*
 32. Lobules subquadrate. Dioicous 33
 33. Lobule base covering more than 1/2 to fully overlapping the stem 34
 33. Lobule base covering up to 1/2 the stem (except on branches of *R. pallens*) 35
 34. Plants irregularly branched. Leaf lobes oblong-ovate. Leaf cells with trigones small at leaf base increasing in size towards the margins, cuticle smooth *R. bahiensis*

34. Plants regularly branched. Leaf lobes ovate. Leaf cells with trigones small, cuticle verruculose
..... *R. recubans*
35. Keel strongly convex. Rhizoid numerous on a pronounced mammiliform swelling of the lobule
..... *R. mammosa*
35. Keel concave to straight. Rhizoid not as above 36
36. Leaves distant to contiguous 37
36. Leaves imbricate 38
37. Lobules rhombic, keel spreading at angles of 30–40° with the stem. Dorsal leaf base not overlapping the stem. Vegetative reproduction by caducous leaf lobes, producing almost completely naked branches *R. pocsii*
37. Lobules subquadrate, keel spreading at angles of 45–50° with the stem. Dorsal leaf base fully overlapping the stem. Vegetative reproduction absent *R. nudicaulis*
38. Leaves suborbicular. Keel straight to concave. Caducous leaf lobes absent *R. pallens*
38. Leaves ovate to falcate-ovate. Keel straight. Caducous leaf lobes present *R. javanica*

Radula angulata Steph., Hedwigia 23: 114. 1884.

Fig. 3

TYPE: Venezuela, Caripe, Moritz 152 (holotype: G-00043973!).

= *Radula korthalsii* Steph., Hedwigia 23: 133. 1884. TYPE: Venezuela, P. W. Korthals 184, ex hb. Sand. Lac. (lectotype: G-00283269!, designated by Yamada 1980). Venezuela. A. Fendler s.n., ex hb. Gottsche (syntype: G-00281267).

Dioicous. PLANTS 1.4–2 mm wide, yellowish-green to yellowish-brown in herbarium, irregularly pinnate. STEMS in cross section with ca. 20 thick-walled epidermal cells surrounding ca. 21 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones large. LEAVES obliquely to widely spreading, imbricate, slightly convex, ovate, 0.7–1.2 mm long, 0.65–0.9 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane, entire; marginal cells subquadrate to isodiametric, 10–20 × 7–10 µm, median cells isodiametric to elongate, 15–25 × 10–15 µm, basal cells elongate, 20–30 × 10–15 µm, cell walls thin, trigones small at leaf base and midleaf, increasing in size towards the margins, cuticle smooth. LOBULES distant to contiguous, (sub)quadrate, 0.75–0.45 mm long, 0.35–0.55 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded to angulate, covering 3/4 to fully overlapping the stem, free margin plane, straight, apex plane, acute to obtuse, distal margin straight; keel straight,

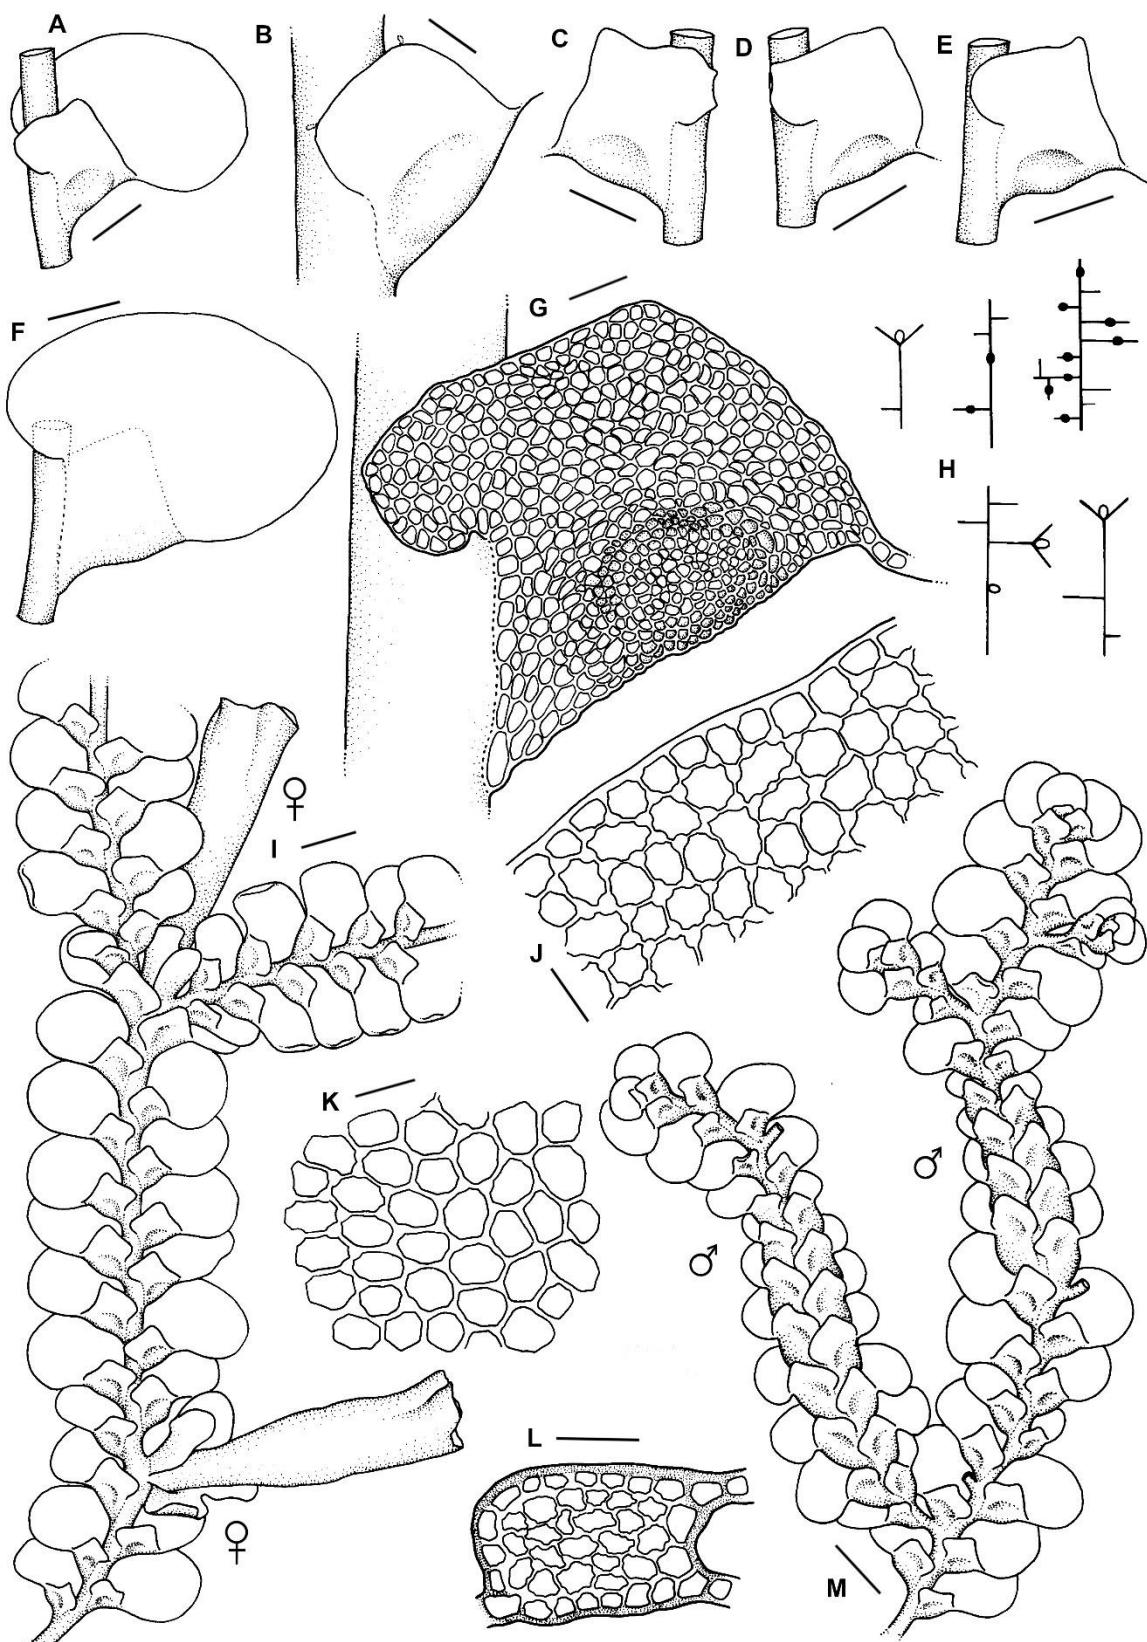

Figure 3. A-M. *Radula angulata* - A. Leaves. B-E, G. Lobules. F. Leaf, dorsal view. H. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). I. Habit with gynoecia. J. Marginal leaf cells. K. Median leaf cells. L. Cross section of a stem. M. Habit with androecia. (A, C-F= 250 µm; B= 100 µm; G, L= 50 µm; I, M= 500 µm; J, K= 25 µm; A, C-F, J-L from the holotype G00043973; B, G-I, M from UFP30030).

spreading at angles of 50–70° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on long branches, with 5–10 pairs of bracts, 0.8–1.1 mm wide; bracts ovate, 0.7–1 mm long, 0.35–0.55 mm wide, apex rounded, margin plane, entire, lobule ovate, ca. 3/4 of lobe length, base rounded to angulate, free margin straight, apex obtuse, rarely subacute. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 0.9–1.1 mm long, 0.4–0.45 mm wide, apex rounded, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2.4–2.8 mm long, 0.65–1.1 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by means of caducous leaf lobes and stem fragmentation.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1964, p. 194–195, Fig. 4), Castle (1966, p. 8–10, Fig. 2 as *R. korthalsii*), Yamada (1980, p. 250–251, Fig. 6 as *R. korthalsii*, 1991, p. 87–88, Fig. 38).

DISTRIBUTION AND HABITAT: West Indies, Colombia, Venezuela, Brazil. In Brazil recorded from Bahia, Espírito Santo, Minas Gerais, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. The species grows in Atlantic forest, usually on tree trunks and decaying wood, at 670–1900 m elevation.

TAXONOMIC NOTES: *Radula angulata* is characterized by (1) plants irregularly pinnate; (2) leaf lobes ovate with entire margins, sometimes caducous; (3) leaf cell walls thin with small to large trigones increasing in size towards the margins; (4) lobules distant to contiguous, (sub)quadrate, base rounded to angulate, covering 3/4 to fully overlapping the stem, apex usually acute, and keel straight.

This species is similar to *R. cubensis*, especially in the lobule shape. *Radula cubensis*, however, has leaves ovate to strongly falcate-ovate, margin plane to undulate, cell walls thin, trigones lacking, and keel straight, spreading at angles of 40–50° with the stem (50–70° in *R. angulata*). *Radula angulata* may also be confused with *R. mexicana* but the latter species is monoicous, trigones are small or lacking, and the lobule base covers up to 1/2 the stem.

Radula bahiensis F.R.Oliveira-da-Silva, Ilk.-Borg. & Gradst., Phytotaxa 454(1): 25. 2020.

Fig. 4

TYPE: Brazil, Bahia, Uruçuca, 6.2 km N of town of Serra Grande, ca. 40 km N of Ilhéus along coast, wet tropical forest with small stream in ravine, 14°26' S, 39°03' W, 200 m, 17 July 1991, Vital & Buck 20271 (holotype: SP-353920!; isotype: MG!).

Dioicous. PLANTS 2–3.5 mm wide, green to olive-green in herbarium, irregularly pinnately branched. STEMS in cross section with ca. 29 thick-walled epidermal cells surrounding ca. 47 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones small. LEAVES widely spreading, imbricate, slightly convex, oblong-ovate, 1–1.8 mm long, 0.6–1.1 mm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin plane, entire to sinuate; marginal cells subquadrate, 12–20(–30) × 10–15 µm, median and basal cells isodiametric to elongate, 20–25(–30) × 15–20 µm, cell walls thin, trigones small at leaf base and midleaf, increasing in size towards the margins, cuticle smooth. LOBULES distant to subimbricate, oblong, 0.7–0.9 mm long, 0.5–0.7 mm wide, ca. 1/2 of the lobe length, inflated along the keel, insertion line ± straight, base plane, rounded, covering 2/3 to fully overlapping the stem, free margin plane, straight, apex rounded to obtuse, distal margin ± straight to rounded; keel straight to sinuate-concave, spreading at angles of 40–50° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal to intercalary on long branches, with 2–4 pairs of bracts, 1.1–1.4 mm wide; bracts ovate, 0.8–1 mm long, 0.3–0.5 mm wide, apex rounded, margin plane, entire to sinuate, lobule distant to contiguous, ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex rounded; keel convex, inflated. GYNOECIA on long branches, with one innovation; bracts oblong-ovate, 1–1.3 mm long, 0.6–0.8 mm wide, apex rounded, margin plane, entire, lobule ovate, ca. 1/3 of lobe length, apex rounded. PERIANTHS not seen. VEGETATIVE REPRODUCTION by stem fragmentation and caducous *Lejeunea*-type branches. (Oliveira-da-Silva et al. 2020).

DISTRIBUTION AND HABITAT: Only known from Bahia, occurring on tree trunks, at 50–200 m elevation.

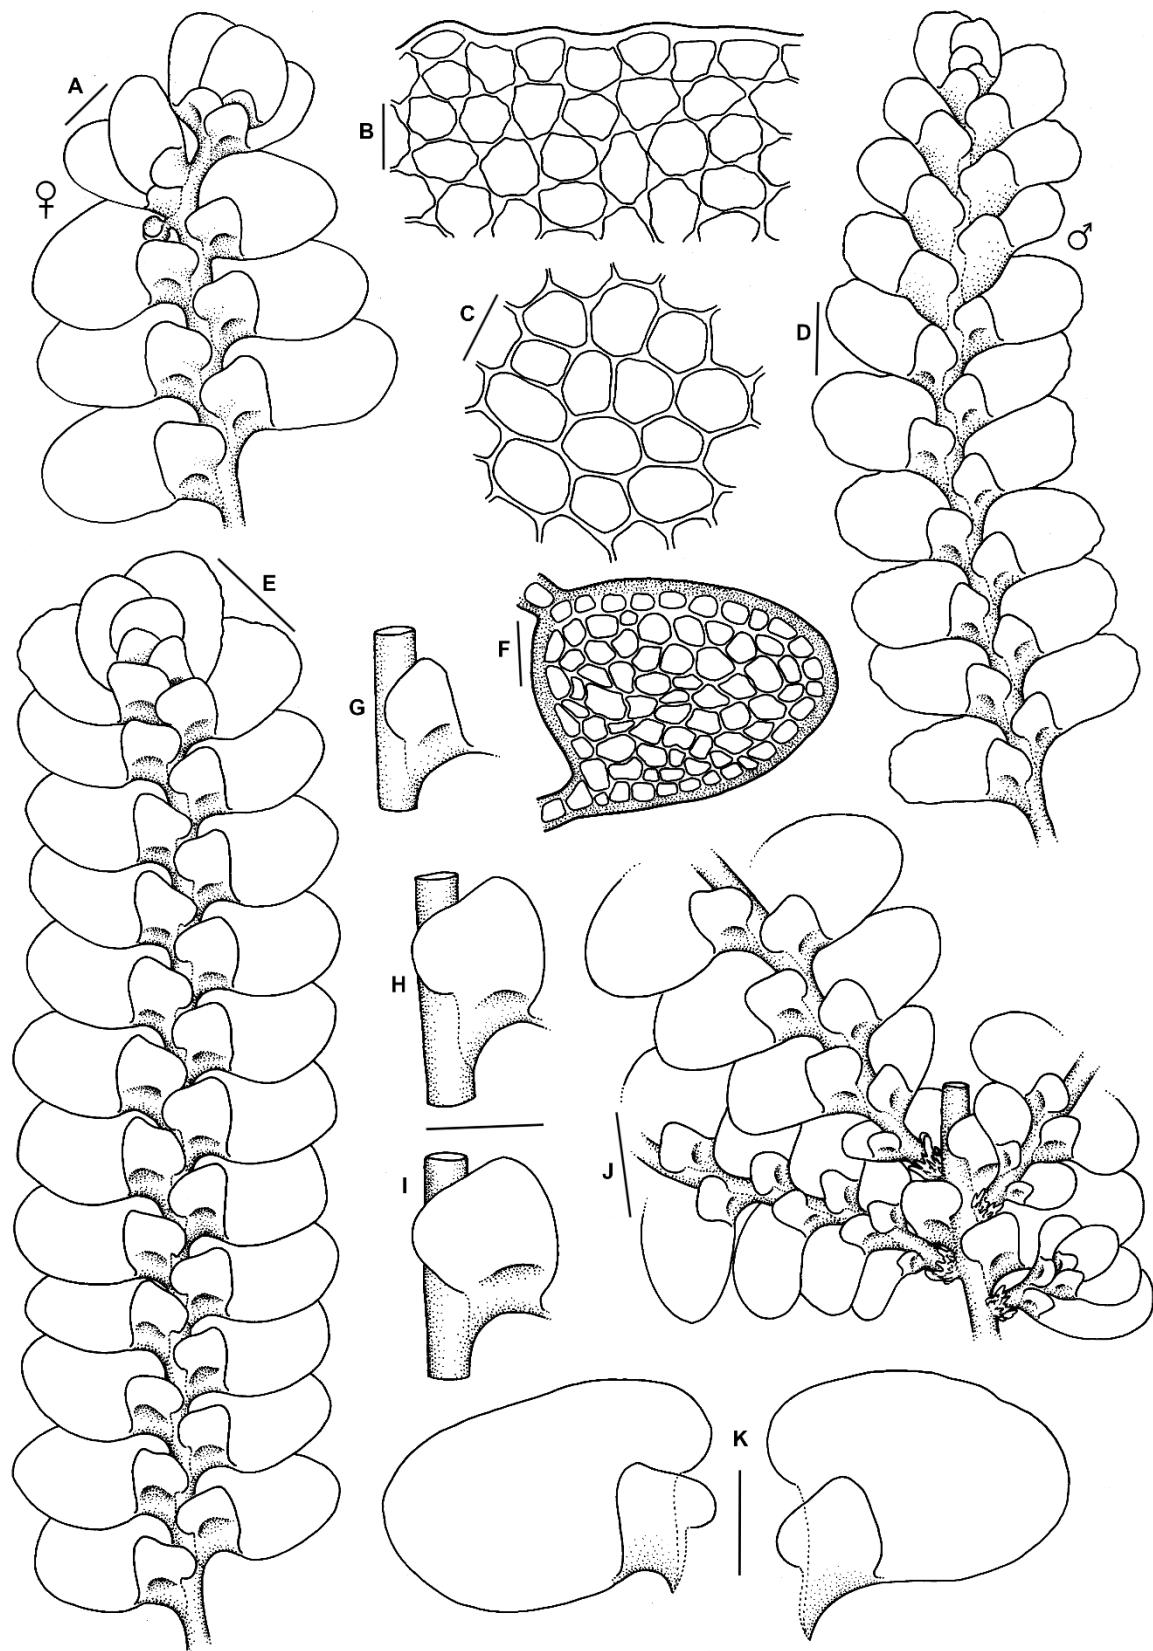

Figure 4. A-K. *Radula bahiensis*. A. Habit with gynoecia. B. Marginal leaf cells. C. Median leaf cells. D. Habit with androecia. E, J. Habit. F. Cross section of a stem. G-I. Lobules. K. Leaves. (A, C, G, H, I, K= 500 μm ; B, D= 25 μm ; F= 50 μm ; E, J= 1000 μm ; A, E from SP353920; D from NY1670325; B, C, F, G, H, I, J, K from SP373105).

TAXONOMIC NOTES: *Radula bahiensis* is recognized by (1) leaves widely spreading, oblong-ovate, apex rounded to obtuse, margin entire to shallowly sinuate; (2) leaf cells with small trigones at base increasing in size towards the leaf margins; (3) lobules oblong with base covering 2/3 to fully overlapping the stem, lobule apex rounded to obtuse, distal margin straight to rounded, and keel straight to sinuate-concave.

The species resembles robust *R. pallens* in leaves widely spreading, and keel straight to concave (Oliveira-da-Silva et al. 2020). *Radula pallens*, however, differs in leaves suborbicular with broadly rounded apex, trigones usually lacking, and lobules (sub)quadrate with base covering 1/4–1/3 the stem.

ADDITIONAL SPECIMEN EXAMINED: **Brazil.** BAHIA: Una, Maruim, border of the fazendas Maruim and Dois de Julho, 33 km SW of Olivença on road from Olivença to Burarema, Southern Bahian wet forest, epiphytic on tree, in full shade, 28 April 1981, Boom et al. 811 (paratype: NY).

Radula brasiliaca K.Yamada, J. Hattori Bot. Lab 74: 35. 1993.

Fig. 5

TYPE: Brazil, São Paulo, Serra de Mantiqueira, Campos do Jordão, “auf morschem Holz im Regenwald am Pico do Itapeva,” 1850 m, 22°45'S, 45°31'W, 13 June 1987, Schäfer-Verwimp & Verwimp 8484 (holotype: NICH-413169!).

Dioicous. PLANTS 0.8–1.4 mm wide, yellowish-green in herbarium, irregularly pinnate. STEMS in cross section with ca. 16 thick-walled epidermal cells surrounding ca. 16 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones lacking. LEAVES widely spreading to squarrose, imbricate, plane to slightly convex, ovate to strongly falcate-ovate, 0.4–0.55 mm long, 0.3–0.4 mm wide, dorsal base rounded, not overlapping the stem, apex rounded to obtuse, margin plane, entire to slightly crenulate; marginal cells subquadrate to isodiametric, 8–20 µm in diam., median cells and basal cells isodiametric to elongate, 15–25 × 10–20 µm, cell walls thin, trigones small, cuticle smooth. LOBULES distant to contiguous, subquadrate, 0.14–0.5 mm long, 0.1–0.4 mm wide, 1/3–1/2 the lobe length, insertion line straight to arched, base recurved, rounded, covering 1/3–1/2 the stem, free margin strongly recurved, apex recurved, rounded to obtuse, distal margin straight; keel straight to strongly convex, spreading at angles of 40–60° with the stem, lobule inflated along the keel. RHIZOIDS colorless, scanty. ANDROECIA terminal to intercalary on long branches, with 3–6 pairs of bracts, 0.65–0.7 mm wide; bracts ovate, 0.7–0.8 mm long, 0.25–0.4 mm wide, apex rounded, margin plane, entire, lobule ovate, ca. 3/4 of lobe length, base obtuse, free margin recurved, apex obtuse. GYNOECIA not seen. VEGETATIVE REPRODUCTION by caducous leaf lobes,

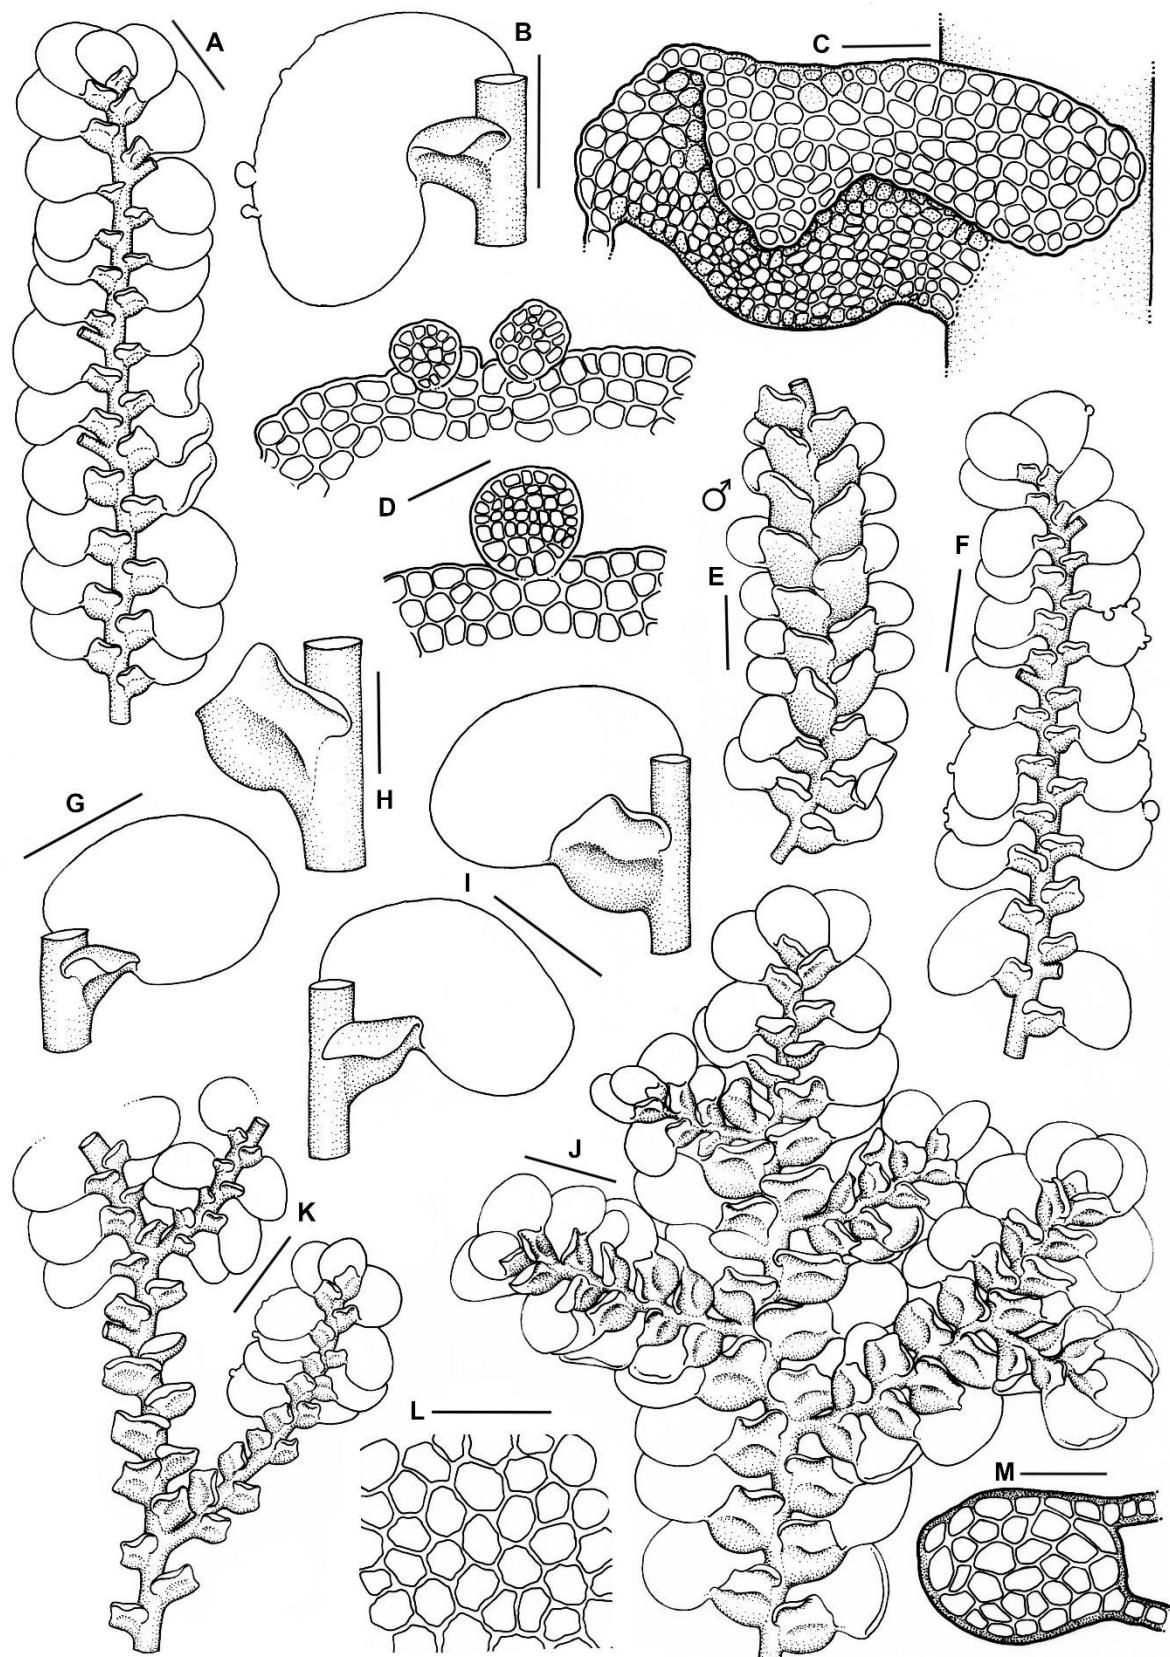

Figure 5. A-K. *Radula brasiliaca* - A, F, J, K. Habit. B, G, I. Leaves. C, H. Lobules. D. Leaf margin with regenerants. E. Habit with androecia. L. Median leaf cells. M. Cross section of a stem. (A, E, F, J, K= 500 μm ; B, G, I= 250 μm ; C, D, L, M= 50 μm ; H= 100 μm ; A-K from holotype NICH-413169).

producing almost completely naked branches, and by small discoid gemmae, ca. 40–65 µm in diam., produced on leaf margins.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1993b, p. 35–37, Fig. 1).

DISTRIBUTION AND HABITAT: Only known from the type from São Paulo State, in Atlantic forest, growing on decaying wood at 1850 m elevation.

TAXONOMIC NOTES: *Radula brasiliaca* differs from other *Radula* species in Brazil by (1) plants small (0.8–0.14 mm wide) and fragile due to caducous leaf lobes often resulting in almost naked branches; (2) leaf lobes ovate to falcate-ovate, with margins entire to slightly crenulate with regenerants; (3) lobules distant to contiguous, subquadrate, with base rounded, recurved, covering 1/3–1/2 the stem, free margin strongly recurved, and keel straight to strongly convex.

Due to the small and fragile plants (with caducous leaf lobes), and the strongly convex keel, *R. brasiliaca* may be confused with *R. schaefer-verwimpii*. However, the latter species has subquadrate to rhombic lobules with the base covering only 1/5–1/3 the stem and free margin plane.

All studied specimens labelled as *R. brasiliaca* in Brazilian herbaria proved to be misidentifications and mostly belong to *R. javanica*. Hitherto, *R. brasiliaca* is only known from the type.

Radula cubensis K.Yamada, J. Hattori Bot. Lab. 54: 241. 1983.

Fig. 6

TYPE: Cuba, Santiago de Cuba, Gran Piedra, on bark, 16 January 1979, D. Reyes M. 1621 (isotype: NICH-400980!).

Dioicous. PLANTS 1–1.7 mm wide, yellowish-green to green in herbarium, irregularly pinnate. STEMS in cross section with 10–12 thick-walled epidermal cells surrounding ca. 11 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish to colorless, trigones lacking. LEAVES widely spreading to squarrose, subimbricate, slightly convex, ovate to strongly falcate-ovate, 0.6–0.9 mm long, 0.4–0.5 mm wide, dorsal base rounded, not overlapping the stem, apex rounded to obtuse, margin plane or weakly undulate; marginal cells subquadrate, 10–15 µm in diam., median and basal cells isodiametric to elongate, 17.5–25 × 12.5–15 µm, cell walls thin, trigones lacking, cuticle smooth. LOBULES distant to contiguous, subquadrate, 0.35–0.45 mm long, 0.25–0.35 mm wide, 1/3–1/2 of the lobe length, inflated at rhizoid area, insertion line straight, base plane to slightly recurved, rounded to obtuse, covering 3/4 to fully overlapping the stem, free margin plane, straight to ± sinuate at middle, apex plane, rounded to obtuse, distal margin straight; keel straight, spreading at

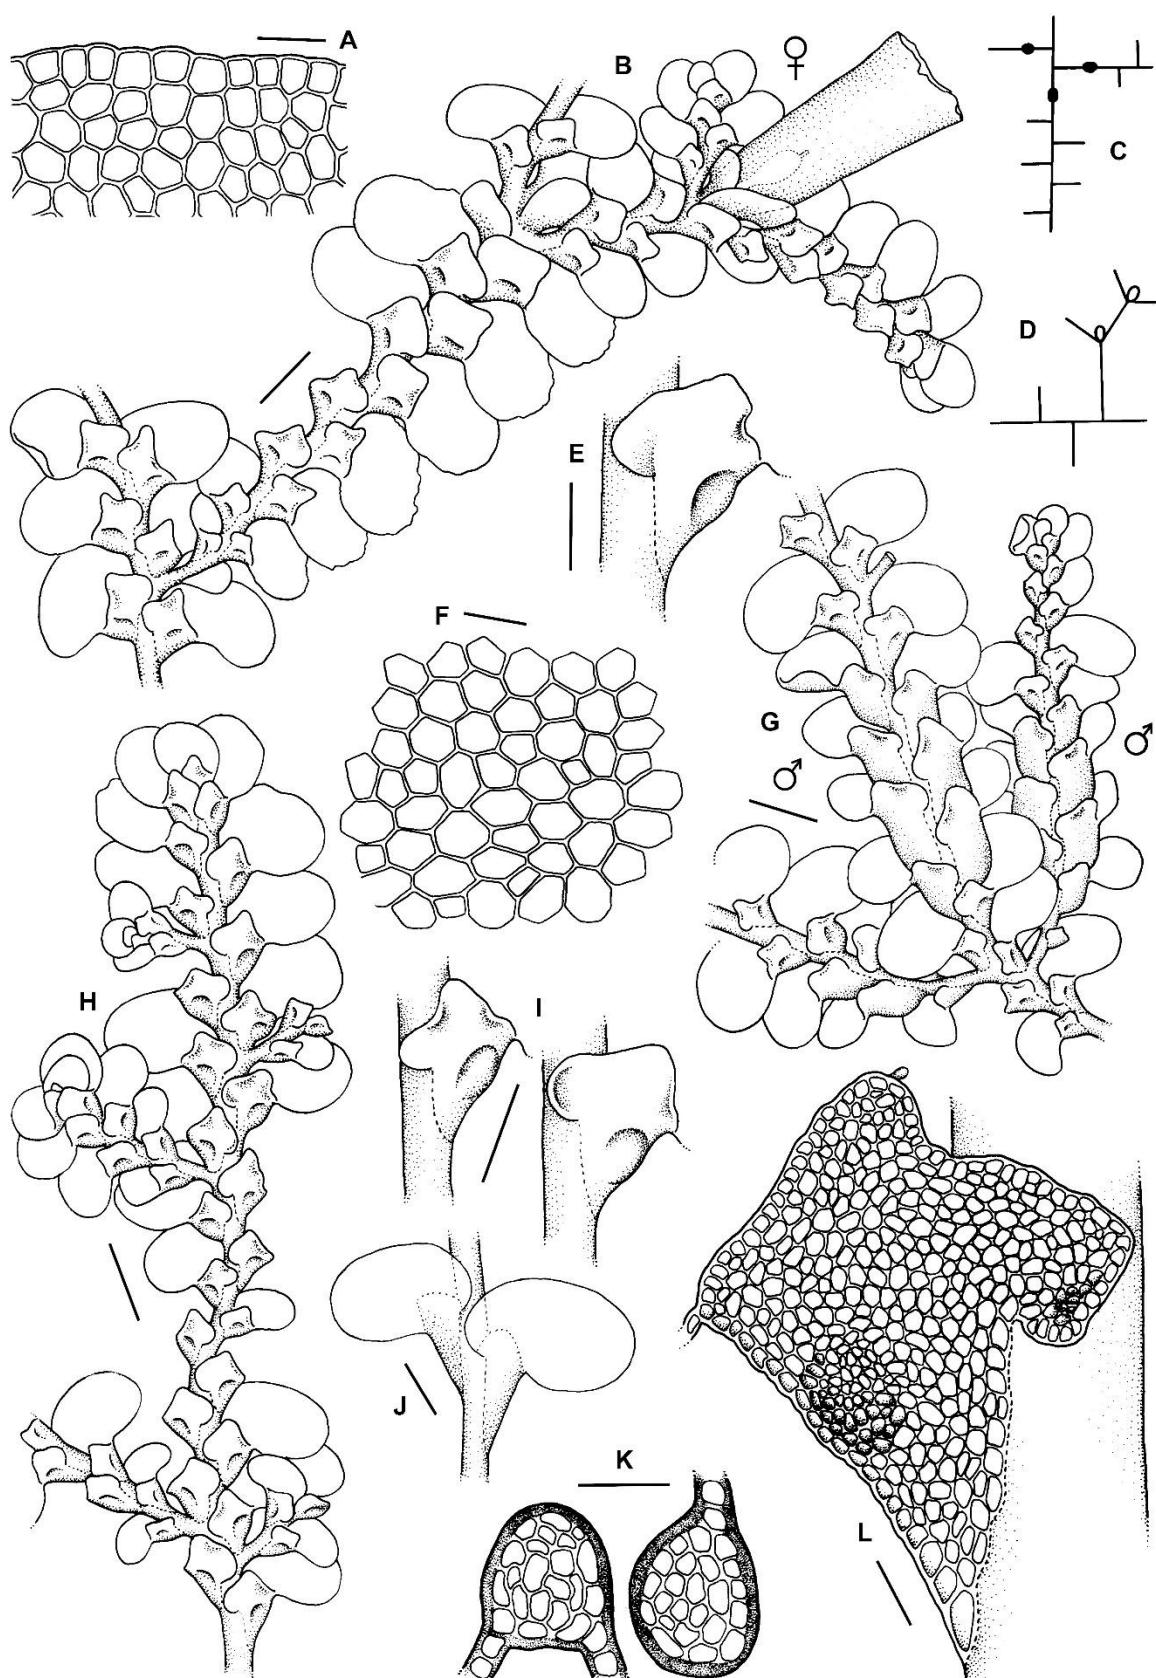

Figure 6. A-L. *Radula cubensis* - A. Marginal leaf cells. B. Habit with gynoecia. C-D. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). E, I, L. Lobule. F. Medium leaf cells. G. Habit with androecia. H. Habit. J. Habit, dorsal view. K. Cross section of a stem. (A, F= 25 μm ; B, G, H= 500 μm ; E, I, J= 250 μm ; K-L= 50 μm ; A, E, F, H-L from Isotype NICH; B, D from UFP17966; C, G from SP42291).

angles of 40–50° with the stem. RHIZOIDS colorless, scanty. ANDROECIA intercalary on long branches, with 2–4 pairs of bracts, 0.9–1.4 mm wide; bracts ovate, 0.7–1 mm long, 0.3–0.5 mm wide, margin entire, plane to recurved, apex obtuse, lobule ovate, ca. 3/4 of lobe length, base acute to obtuse, free margin straight, apex obtuse, rarely subacute. GYNOECIA on long branches, with 2 innovations; bracts ovate, 0.8–1 mm long, 0.4–0.5 mm wide, apex rounded, margin plane, entire, lobule oblong, ca. 1/2 the lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, ca. 1.9 µm long, ca. 0.8 µm wide at apex, mouth irregularly undulate. VEGETATIVE REPRODUCTION by caducous leaf lobes, producing almost naked branches.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1983, p. 241–243, Fig. 1).

DISTRIBUTION AND HABITAT: Dominican Republic, Jamaica, Cuba, Ecuador, and Brazil. In Brazil recorded from Bahia, Espírito Santo, Minas Gerais, Pará, Paraná, Pernambuco, Rio Grande do Sul, Santa Catarina and São Paulo. This species usually colonizes tree trunks or decaying wood at 20–1250 m elevation.

TAXONOMIC NOTES: *Radula cubensis* presents the following diagnostic characters: (1) plants fragile, with almost naked branches due to caducous leaf lobes; (2) leaves ovate to strongly falcate-ovate with plane to weakly undulate margins; (3) leaf cell walls thin, trigones lacking; (4) lobule distant to contiguous, base plane to slightly recurved, rounded to obtuse, covering 3/4 to fully overlapping the stem, free margin straight to ± sinuate at middle, apex rounded to obtuse, and keel straight.

Radula cubensis is morphologically similar to *R. angulata*, especially in lobule shape (see discussion under *R. angulata*). The species also resembles *R. javanica* in the falcate-ovate leaves and absence of trigones. However, the latter species differs in the lobule apex varying from obtuse to (rarely) acute and lobule base rounded, covering up to 1/2 the stem.

SELECTED EXAMINED SPECIMENS: **BRAZIL.** BAHIA: Igrapiúna, Reserva Ecológica de Michelin, 13°48'S, 39°10'W, 15 February 2006, Bastos 4217 (ALCB). Fig. 7

TYPE: Venezuela, Valencia, 1856, Fendler s.n., ex hb. Gottsche (lectotype: G-00121933!, designated by Yamada 1987).

Dioicous. PLANTS 1.3–1.7 mm wide, green to brownish in herbarium, irregularly pinnate branched. STEMS in cross section with ca. 15 thick-walled epidermal cells surrounding ca. 13 thick-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls yellowish, trigones large. LEAVES obliquely to widely spreading, imbricate, strongly convex, suborbicular, 0.5–0.9 mm long, 0.4–0.7 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin entire, slightly recurved; marginal cells subquadrate, 10–12.5 μm in diam., median and basal cells isodiametric to elongate, 20–25 \times 10–20 μm , cell walls thin, trigones small at leaf base and midleaf, increasing in size towards the margins, cuticle smooth. LOBULES distant to contiguous, subquadrate, 0.75–0.45 mm long, 0.35–0.55 mm wide, ca. 1/2 the lobe length, inflated, insertion line \pm straight, base plane, rounded, covering 3/4 or less of the stem, free margin plane, straight, apex plane, rounded; keel convex, spreading at angles of 60–70° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on long branches, with 2–3 pairs of bracts, 0.8–1 mm wide; bracts distant to imbricate, ovate, 0.6–0.8 mm long, 0.3–0.4 mm wide, margin entire, plane, rarely recurved, apex rounded, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin \pm straight, apex obtuse. GYNOECIA not seen. VEGETATIVE REPRODUCTION not observed.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1963, p. 15–17, Fig. 6), Solari (1978, p. 185–187, Fig. 3), Yamada (1987, p. 292–294, Figs. 33–34).

DISTRIBUTION AND HABITAT: Guadeloupe, Martinique, Ecuador, Venezuela, Brazil and Chile. In Brazil only known from Pernambuco and São Paulo, growing on bark of living trees and on rock at 50–900 m elevation.

TAXONOMIC NOTES: *Radula decora* is recognized by (1) leaves imbricate, strongly convex, suborbicular, with margin slightly recurved; (2) leaf cell walls thin, trigones small, increasing in size towards the leaf margins; (3) lobules subquadrate, inflated, with rounded base, covering up to 3/4 the stem, and keel convex. This is the only species of subg. *Odontoradula* in Brazil.

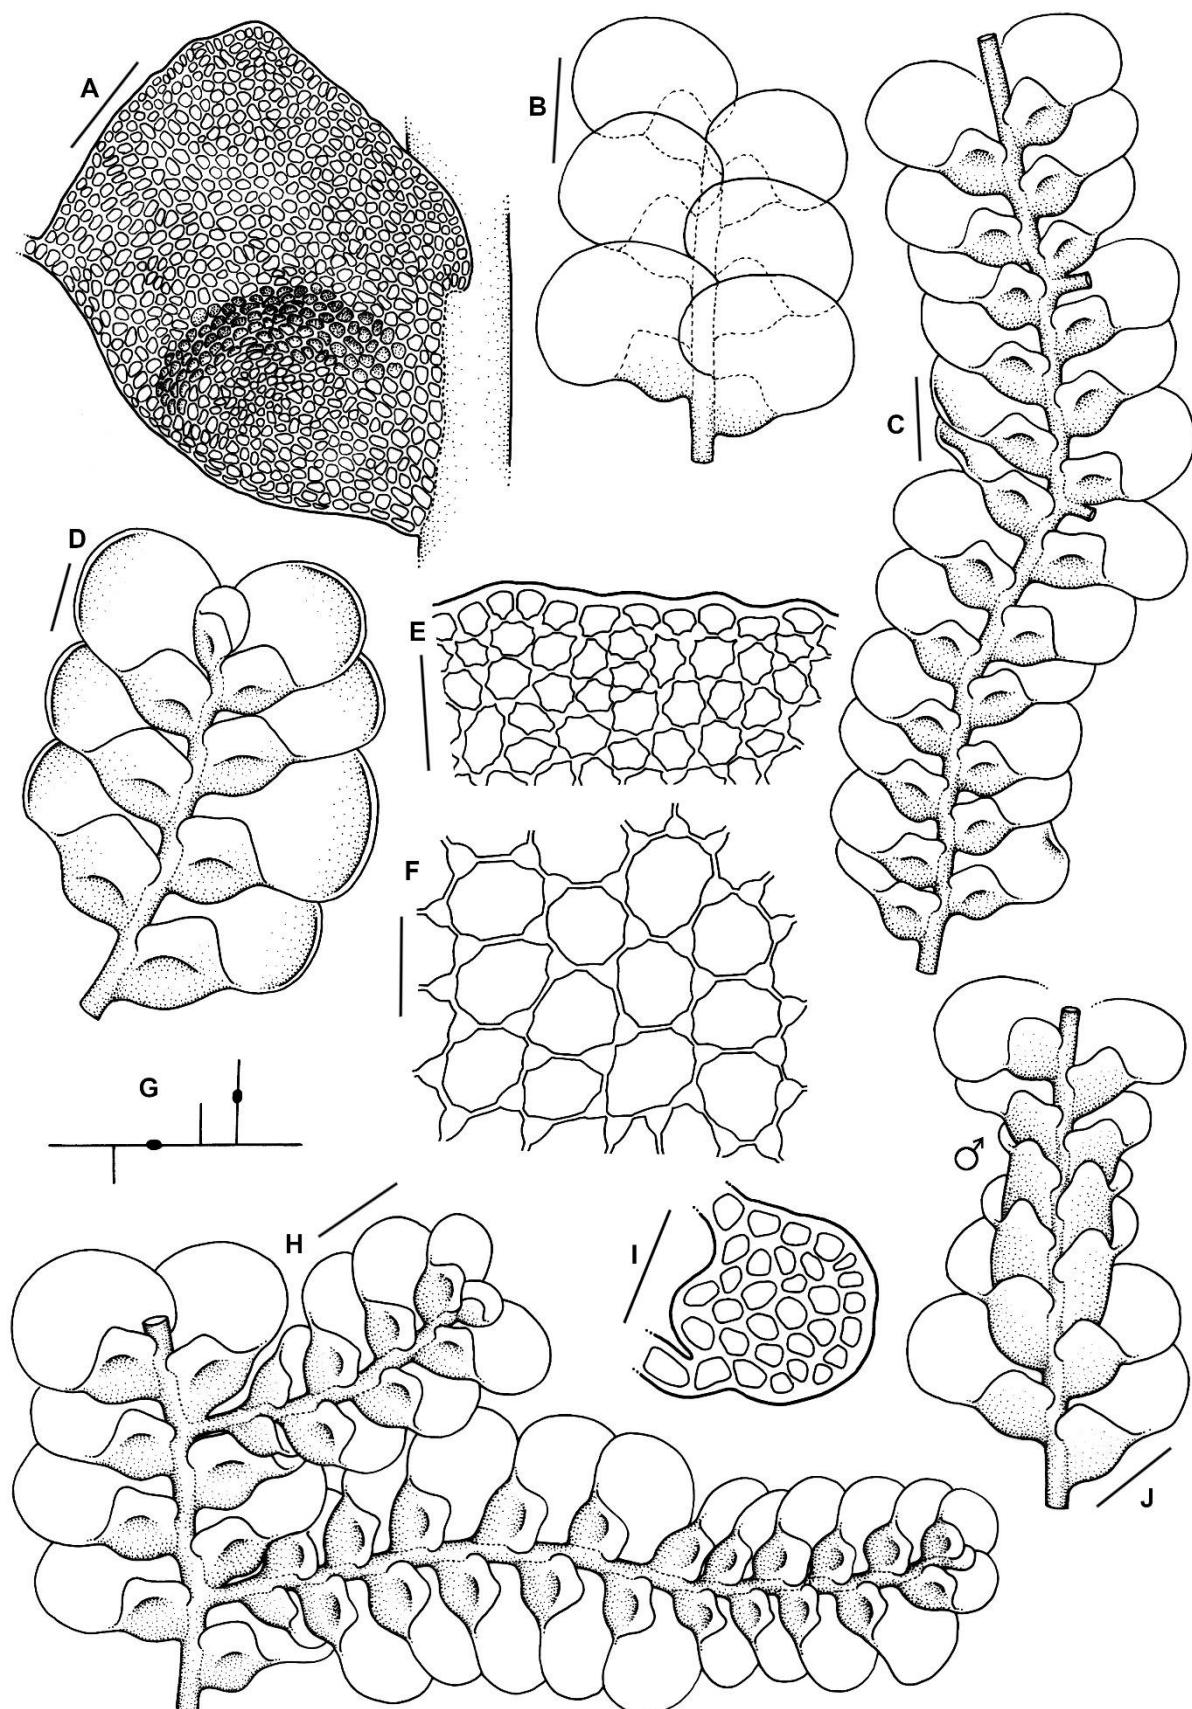

Figure 7. A-J. *Radula decora* - A. Lobule. B. Habit dorsal view. C, D, H. Habit. E. Marginal leaf cells. F. Median leaf cells. G. Cladograph of fertile plants (solid ellipse= androecia). I. Cross section of a stem. J. Habit with androecia. (A= 100 μm ; B, C, H, J= 500 μm ; D= 250 μm ; E, I= 50 μm ; F= 25 μm ; A, D, F, I from lectotype G00121933; B, C, E, G, H from UFP17962).

According to Yamada (1987), *Radula decora* is closely similar to *R. saccatiloba* (species excluded from Brazil), but the lobules in *R. saccatiloba* are narrowly inflated along the keel and flattened above while those in *R. decora* are completely inflated. Schiffner & Arnell (1964) recorded *R. decora* from São Paulo State; this record needs verification. From the specimens deposited in Brazilian herbaria as *R. decora*, only two collections, from Pernambuco and São Paulo, are *R. decora*. Others belong to *R. javanica*, *R. angulata* or *R. pallens*.

SELECTED EXAMINED SPECIMENS: **Brazil.** PERNAMBUCO: Caruaru, Brejo dos Cavalos, 27 August 1987, Pôrto 2624i (UFP). SÃO PAULO: Mogi das Cruzes, propriedade da Suzano, Mata Atlântica, base do morro Pedra do Garrafão, 23°39'26"S, 46°01'54"W, 980 m, 15 June 2007, Peralta et al. 5053 (SP).

Radula fendleri* Steph. var. *fendleri, Hedwigia 23: 146. 1884.

Fig. 8

TYPE: Venezuela, Valencia, "in cortice repens," Fendler s.n. (lectotype: G-00121978!, designated by Yamada 1980). Guadeloupe, L'Herminier s.n., ex hb. Gottsche (syntype: G-00281263!).

Dioicous. PLANTS 1–1.8 mm wide, green to brownish in herbarium, irregularly pinnate. STEMS in cross section with ca. 17 thick-walled epidermal cells surrounding ca. 12 thick-walled medullary cells, epidermal and medullary cells of the same size, cell walls brown, trigones large. LEAVES widely spreading, imbricate, strongly convex, ovate to falcate-ovate, 0.7–1 mm long, 0.5–0.7 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin strongly recurved, entire; marginal cells subquadrate, 5–15 μm in diam., median and basal cells isodiametric, 20–25 \times 15–20 μm , cell walls thin, trigones large, cuticle verruculose. LOBULES distant, subrectangular, 0.3–0.5 mm long, 0.1–0.25 mm wide, ca. 1/2 the lobe length, inflated along the keel, insertion line slightly arched, base plane, rounded, covering 1/3(–1/2) the stem, free margin plane, straight, apex plane, rounded, rarely obtuse, distal margin straight; keel convex, spreading at angles of 50–60° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on short branches, with 2–5 pairs of bracts, 0.8–0.9 mm wide; bracts ovate, 0.4–0.6 mm long, 0.2–0.3 mm wide, apex rounded, margin strongly recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded to obtuse, free margin straight, apex rounded to obtuse. GYNOECIA on long branches, with two innovations, innovations usually rudimentary; bracts ovate, 0.7–0.9 mm long, 0.4–0.5 mm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex obtuse. PERIANTHS subcylindrical, 1.4–2.2 μm long, 0.7–0.8 μm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by caducous leaf lobes.

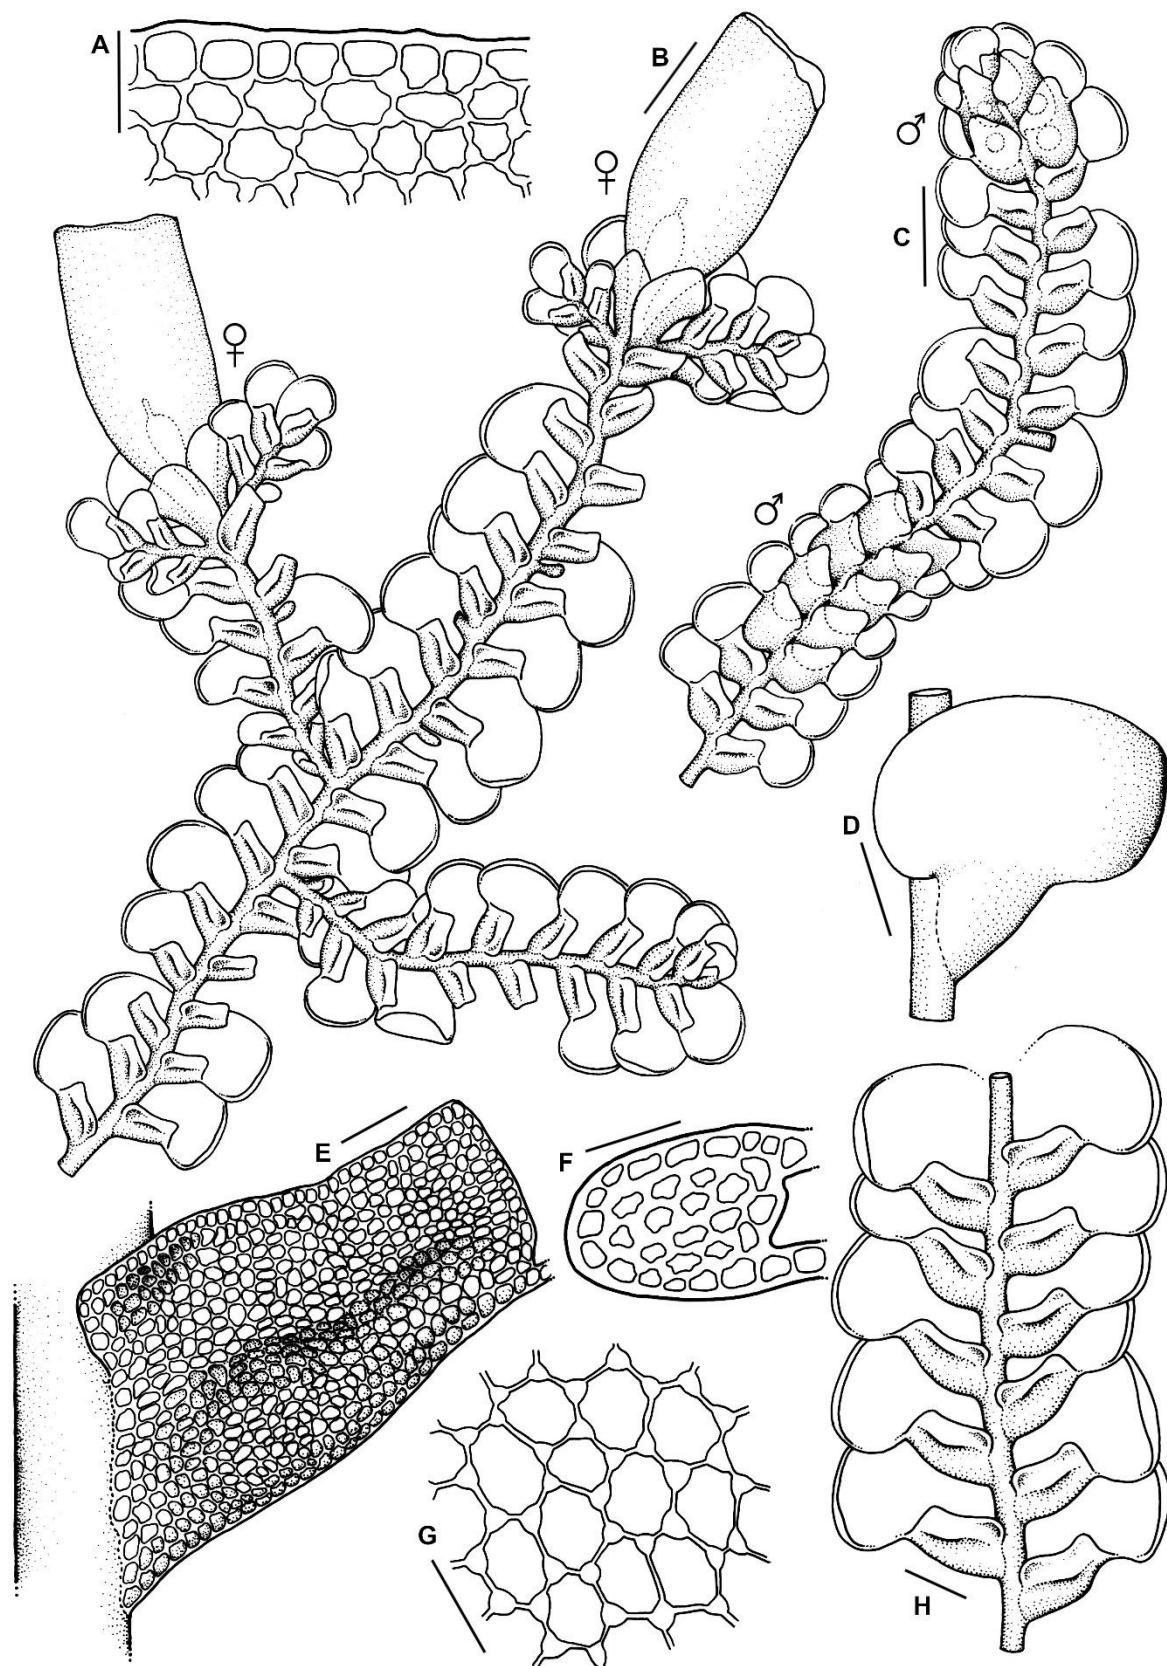

Figure 8. A-J. *Radula fendleri* var. *fendleri*. A. Marginal leaf cells. B. Habit with gynoecia. C. Habit with androecia. D. Leaf, dorsal view. E. Lobule. F. Cross section of a stem. G. Median leaf cells. H. Habit. (A, G= 25 μ m; B, C= 500 μ m; D, H= 250 μ m; E, F= 50 μ m; A, D-H from syntype G00281263; B from SP395292; C from SP280213).

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1963, p. 5–7, Fig. 1), Yamada (1980, p. 244–246, Fig. 2).

DISTRIBUTION AND HABITAT: West Indies and tropical South America. In Brazil recorded from Bahia, Minas Gerais, Paraná, Rio Grande do Sul and São Paulo. The species grows in Atlantic forest, usually on tree trunks at 450–2400 m elevation.

TAXONOMIC NOTES: *Radula fendleri* is characterized by (1) caducous leaf lobes; (2) leaves ovate, strongly convex, with strongly recurved margin; (3) leaf cells with large trigones and cuticle verruculose; (4) lobules distant, subrectangular (longer than wide), inflated along the keel and flattened above, base covering ca. 1/3 the stem, apex rounded to obtuse.

This species resembles *R. pseudostachya* in the production of caducous leaf lobes, leaf margin strongly recurved, cells with large trigones, and cuticle verruculose. However, *R. pseudostachya* differs by lobule contiguous to subimbricate, 0.4–0.6 × 0.25–0.4 mm (0.3–0.5 × 0.1–0.25 mm in *R. fendleri*), and base covering 1/2 to fully overlapping the stem. Moreover, *R. fendleri* usually produces few caducous leaf lobes whereas in *R. pseudostachya* caducous leaves are produced in great abundance, leaving most branches almost completely naked.

SELECTED EXAMINED SPECIMENS: **BRAZIL.** BAHIA: Abaíra, Campo de Ouro Fino (baixo), 13°15'N, 41°54'W, 1600–1700 m, 18 January 1992, Hind & Queiroz 50091 (SP). mm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin strongly recurved, entire; marginal cells subquadrate, 7–10 μm in diam., median and basal cells isodiametric to elongate, 15–25 \times 10–15 μm , cell walls thin, trigones lacking to small, cuticle verruculose. LOBULES distant, subrectangular, 0.3–0.5 mm long, 0.1–0.3 mm wide, ca. 1/2 the lobe-length, strongly inflated along the keel, insertion line slightly arched, base plane, rounded, covering 1/3(–1/2) the stem, free margin plane, \pm straight, apex plane, rounded, rarely obtuse, distal margin \pm straight; keel arched, spreading at angles of 45–60° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal or preceding the gynoecia, on short branches, with 1–3 pairs of bracts, 0.55–1 mm wide; bracts ovate, 0.45–0.75 mm long, 0.2–0.4 mm wide, apex rounded, margin strongly recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded to obtuse, free margin \pm straight, apex rounded to obtuse. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 0.75–1 mm long, 0.55–0.6 mm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex obtuse. PERIANTHS subcylindrical, 1.8–2.2 mm long, 0.65–0.9 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION not observed. (Oliveira-da-Silva et al. 2020).

DISTRIBUTION AND HABITAT: This variety is only known from the type from Rio de Janeiro State, growing on decaying wood in Atlantic forest.

TAXONOMIC NOTES: The new variety differs from the typical one by plants paroicous (dioicous in var. *fendleri*), leaf cells with small trigones or without trigones (large in var. *fendleri*), and absence of caducous leaves (caducous leaves present in var. *fendleri*) (Oliveira-da-Silva et al. 2020).

Radula flaccida Lindenb. & Gottsche, Syn. Hepat. 726. 1847.

TYPE: Mexico, “Prope Hacienda de Fovo foliis Psychotriae cuiusdam arctissime irrepens,” Liebmann s.n. (lectotype: BM-000969204!, designated here; isolectotypes: S-B43094!, S-B43089!).

= *Radula epiphylla* Mitt., Hedwigia 23: 151. 1884. TYPE: Niger, Barter s.n. (lectotype: NY-00831329!, designated here; isolectotypes: NY-00831330!, NY-00831331!).

Dioicous. PLANTS 1–1.5 mm wide, yellowish-green to green in herbarium, irregularly pinnate, rarely bipinnate. STEMS in cross section 9–11 thin-walled epidermal cells surrounding 3–4 thin-walled medullary cells, epidermal and medullary cells of the same size, cell walls colorless, trigones lacking. LEAVES obliquely to widely spreading, contiguous to subimbricate, slightly convex, ovate to \pm obovate, 0.6–0.8 (–0.9) mm long, 0.35–0.65 mm wide, dorsal base rounded, not overlapping the stem, apex rounded, margin plane, entire to strongly crenulate on dorsal margin

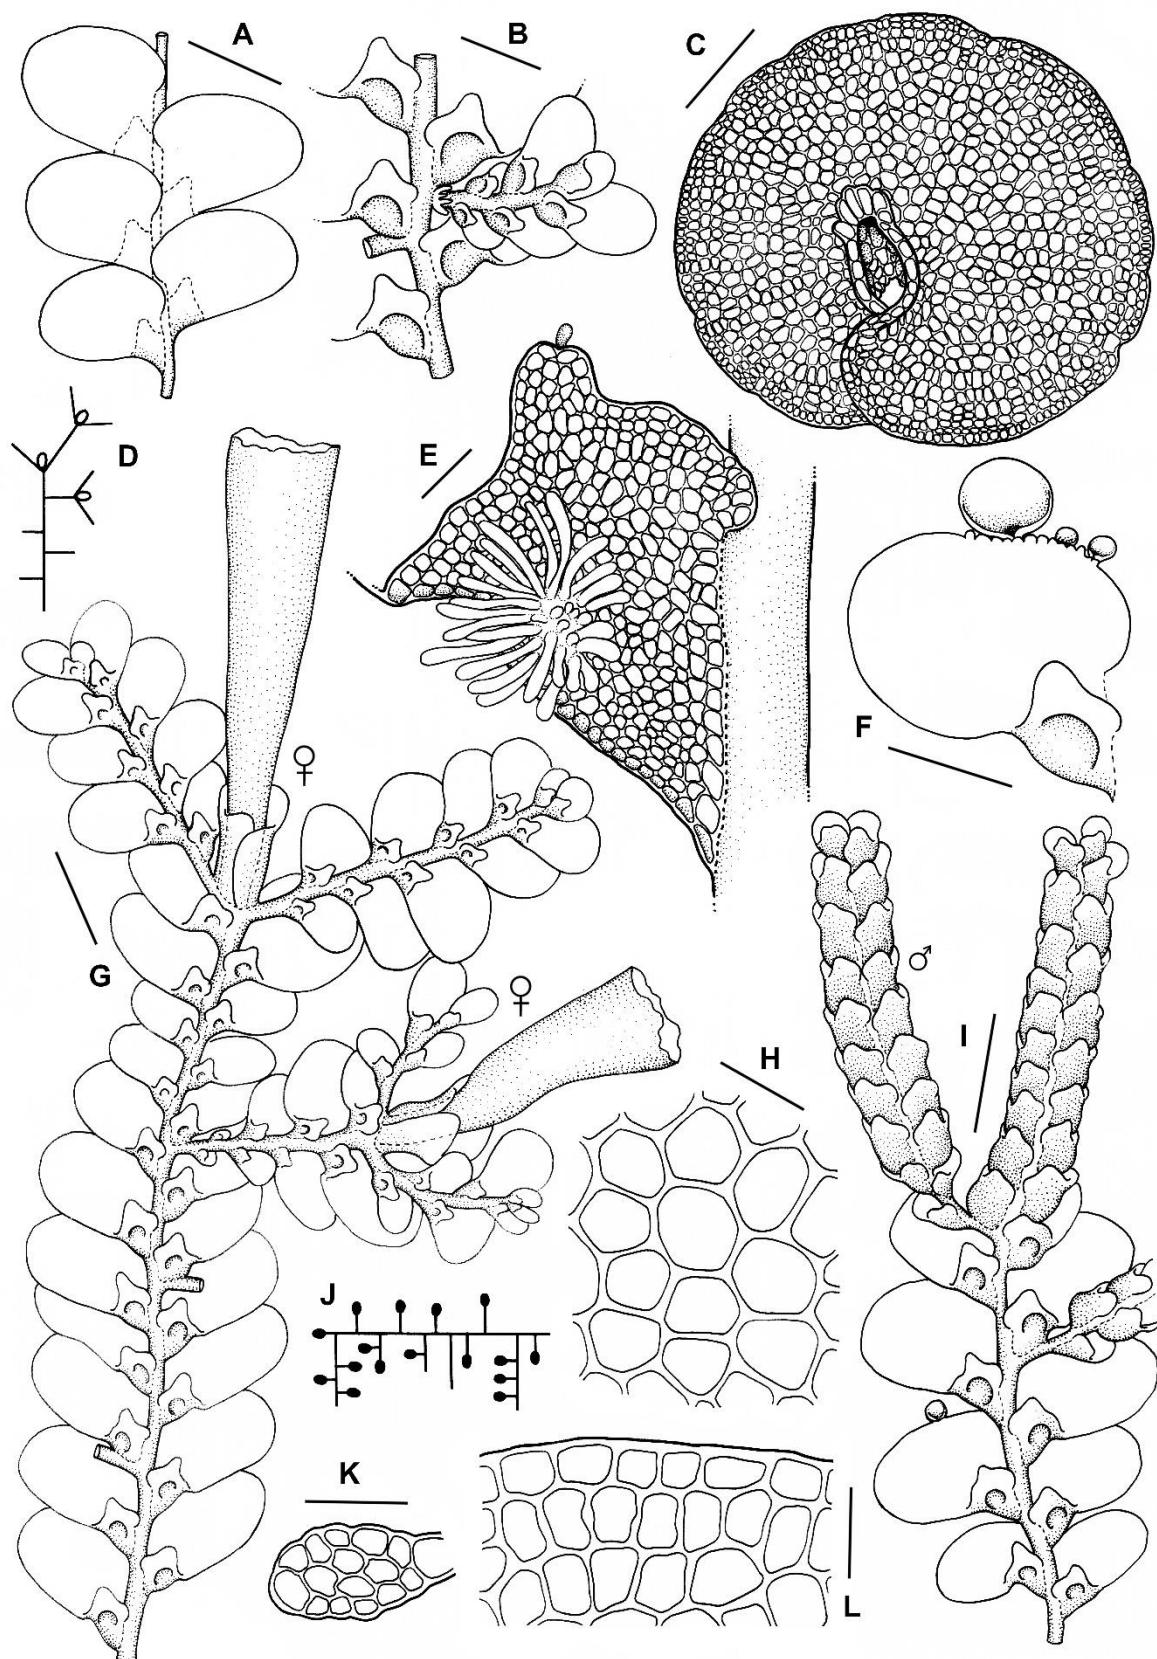

Figure 10. A-L. *Radula flaccida* – A. Habit, dorsal view. B. Habit with *Lejeunea*-type branches. C. Gemmae. D, J. Cladograph of fertile plants (open ellipse= gynoecia, solid ellipse= androecia). E. Lobule. F. Leaf with gemma. G. Habit with gynoecia. H. Median leaf cells. I. Habit with androecia. J. Cross section of a stem. L. Marginal leaf cells (A, G, I= 500 μm ; B, F= 250 μm ; C= 100 μm ; E, K= 50 μm ; H, L= 25 μm ; A, D, E, F, H, L from MG171633; B, J from SP433662; C, K from MG174047; G, I from SP134581).

when with gemmae; marginal cells subquadrate, 5–12 µm in diam., median and basal cells isodiametric to elongate, 25–38 × 12–25 µm, cell walls thin, trigones small, cuticle smooth. LOBULES distant, (sub)quadrate, 0.15–0.3 (–0.4) mm long, 0.1–0.2 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line ± straight, base plane, covering 1/5–1/4 the stem, free margin plane, straight to sinuate, apex plane, extended towards an obtuse tip, distal margin straight; keel convex, spreading at angles of ca. 60° with the stem. RHIZOIDS colorless to brown, numerous on a pronounced mammiliform swelling. ANDROECIA intercalary to usually terminal on long branches, with 5–12 pairs of bracts, 0.3–0.4 mm wide; bracts ovate, 0.25–0.35 mm long, 0.1–0.25 mm wide, apex rounded, margin recurved, entire, lobule ovate, ca. 5/6 of lobe length, base slightly rounded to straight, free margin straight, apex rounded to obtuse. GYNOECIA on long branches, with two innovations; bracts oblong-ovate, 0.5–0.6 mm long, 0.15–0.2 mm wide, apex rounded to obtuse, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS trumpet-shaped, 2–2.5 mm long, 0.3–0.4 mm wide at apex, projected away from the substrate, mouth irregularly undulate. VEGETATIVE REPRODUCTION by caducous *Lejeunea*-type branches and by large discoid gemmae, produced on dorsal leaf margins, 1–3 per leaf, 0.35–0.45 mm in diam., base of gemmae deeply cordate-auriculate, opposite auricles touching to overlapping each other.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1925, p. 441–445, Fig. 11, 1939, p. 28–32, Fig. 4), Schuster (1980, p. 648–651, Fig. 635), Zartman & Ilkiu-Borges (2007, p. 108 and 129, Fig. 21D–F), Gradstein & Ilkiu-Borges (2009, p. 40–41, Fig. 22D–G).

DISTRIBUTION AND HABITAT: Tropical America and Tropical Africa. In Brazil known from Acre, Alagoas, Amapá, Amazonas, Bahia, Espírito Santo, Minas Gerais, Mato Grosso, Pará, Paraíba, Pernambuco, Rondônia and Roraima. This species usually grows on living leaves, rarely on bark, at 30–550 m elevation.

TAXONOMIC NOTES: *Radula flaccida* is characterized by (1) plants forming rounded patches on the surface of living leaves; (2) lobules distant, (sub)quadrate with a pronounced mammiliform swelling at the rhizoidal area and apex extended towards an obtuse tip; (3) vegetative reproduction by large discoid gemmae with a deeply cordate-auriculate base, produced on dorsal leaf margins; (4) perianth trumpet-shaped, projected away from the substrate.

Radula flaccida shares the usual occurrence on living leaves and the production of discoid gemmae with *R. yanoella* and *R. stenocalyx*. However, gemmae in *R. flaccida* are very large, with a cordate-auriculate base, and are produced only on the dorsal leaf margin. In *R. yanoella* and *R. stenocalyx*, in contrast, gemmae are much smaller, not cordate-auriculate at base, and are produced all along the leaf margins.

concave, spreading at angles of ca. 60–70° with the stem. RHIZOIDS not seen. ANDROECIA terminal to intercalary on long branches, with 3–6 pairs of bracts, 1.1–1.4 mm wide; lobes distant to contiguous, ovate, 0.7–1 mm long, 0.25–0.35 mm wide, apex rounded, margin plane, entire, lobules imbricate, oblong, ca. 5/6 the lobe length, base rounded to obtuse, free margin straight, apex obtuse. GYNOECIA and VEGETATIVE REPRODUCTION not seen.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1988, p. 389), Yamada & Gradstein (1991, p. 65).

DISTRIBUTION AND HABITAT: Tropical America. In Brazil recorded from Amazonas, Minas Gerais, Paraná, Rio de Janeiro and São Paulo. This species usually grows on bark of living trees and rock, at 450–1200 m elevation.

TAXONOMIC NOTES: *Radula gottscheana* has several distinct characters separating it from other *Radula* species in Brazil, including (1) stems with a thick-walled, brown, 2–4-layered cortex; (2) leaves with obtuse to subacute apex; (3) leaf cells with large trigones; (4) lobules with a strongly auriculate base extending downwards beyond the keel.

Among Brazilian species, *R. gottscheana* can only be confused with *R. voluta*; both are large plants with strongly auriculate lobule bases. However, the keel in *R. voluta* is much longer than in *R. gottscheana* and the auriculate lobule base does not extend downwards beyond the keel.

Dioicous. PLANTS 1.8–3 mm wide, green to yellowish-brown in herbarium, irregularly pinnate. STEMS in cross section with ca. 21–62 thick-walled epidermal cells surrounding ca. 18–180 thick-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls brown, trigones large. LEAVES obliquely to widely spreading, sometimes squarrose, distant to imbricate, slightly convex, ovate to falcate-ovate, 0.8–1.5 mm long, 0.5–1 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane to slightly recurved, entire; marginal cells subquadrate, 10–15 × 8–12 µm, median and basal cells isodiametric to elongate, 15–30 × 8–15 µm, cell walls thin, trigones small to usually lacking, cuticle smooth. LOBULES distant, (sub)quadrate, 0.5–0.8 mm long, 0.3–0.5 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded, covering up to 1/2 the stem, free margin plane, straight, apex plane, rounded to subacute, distal margin straight; keel straight, rarely slightly convex, spreading at angles of 35–50° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on long branches, with 3–20 pairs of bracts, 0.8–1.7 mm wide; bracts distant to imbricate, ovate, 0.7–1 mm long, 0.3–0.5 mm wide, apex rounded, margin plane to recurved, entire, lobule ovate, 3/4–1/2 of lobe length, base rounded, free margin straight, apex rounded to obtuse. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 1–1.3 mm long, 0.5–0.7 mm wide, apex rounded, margin plane to recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2.5–3.4 mm long, 0.85–1 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by means of caducous leaf lobes and regenerants.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1966, p. 13–15, Fig. 4 as *R. elegans*, p. 15–17, Fig. 5 as *R. surinamensis*, p. 18–19, Fig. 6 as *R. caldana*, p. 19–22, Fig. 7 as *R. longifolia*, p. 22–25, Fig. 8 as *R. amazonica*, p. 58–61, Fig. 26 as *R. sandei*, p. 70–72, Fig. 32 as *R. cordiloba*, p. 72–75, Fig. 33 as *R. javanica*), Yamada (1979, p. 93–97, Figs. 42–45 as *R. surinamensis*, 2003 Fig. 83C), Lemos-Michel (2001, p. 160–162, Fig. 45 as *R. macrostachya*), So (2005, p. 187–188, 2006, p. 217–219), Renner (2005, p. 60–63, Figs. 47–51, 2014, p. 128–141, Figs. 8–17), Gradstein & Ilku-Borges (2009, p. 41–42, Fig. 23A–C).

DISTRIBUTION AND HABITAT: Pantropical. In Brazil known from Acre, Alagoas, Amapá, Amazonas, Bahia, Espírito Santo, Minas Gerais, Pará, Paraíba, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Rondônia, Roraima, Santa Catarina and São Paulo. The species occurs in different domains in Brazil, mostly in the Atlantic Forest region and Amazonia, on tree trunks and decaying wood, rarely on rock, soil and living leaves, from sea level to 2000 m elevation.

TAXONOMIC NOTES: *Radula javanica* is characterized by (1) caducous leaf lobes; (2) leaves ovate to falcate-ovate; (3) lobules distant, (sub)quadrate with base covering up to 1/2 the stem, apex

rounded to subacute, keel usually straight. Leaf shape and cell size are rather variable, and Yamada (2000) considered *R. javanica* “as one of the most plastic... species of *Radula*”. The variability of *R. javanica*, as defined by Yamada and other authors, probably explains its numerous synonyms (Castle 1966, Yamada, 1979, 2000, So 2005, 2006).

This species may be confused with several other *Radula* species in Brazil, especially with *R. brasiliaca* and *R. recubans* (see comments under the latter species).

Radula ligula Steph., Sp. Hepat. 4: 228. 1910.

Fig. 14

TYPE: Brazil, Rio Grande, Lindmann “inter B 174” (holotype: G-00043905!).

Dioicous. PLANTS 1.2–2.8 mm wide, olive-green to brown in herbarium, irregularly pinnate, rarely bipinnate. STEMS in cross section with ca. 20 thick-walled epidermal cells surrounding 20–23 thin-walled medullary cells, epidermal and medullary cells of the same size, cell walls colorless, trigones large. LEAVES widely spreading, contiguous to imbricate, slightly convex, ovate, 0.75–

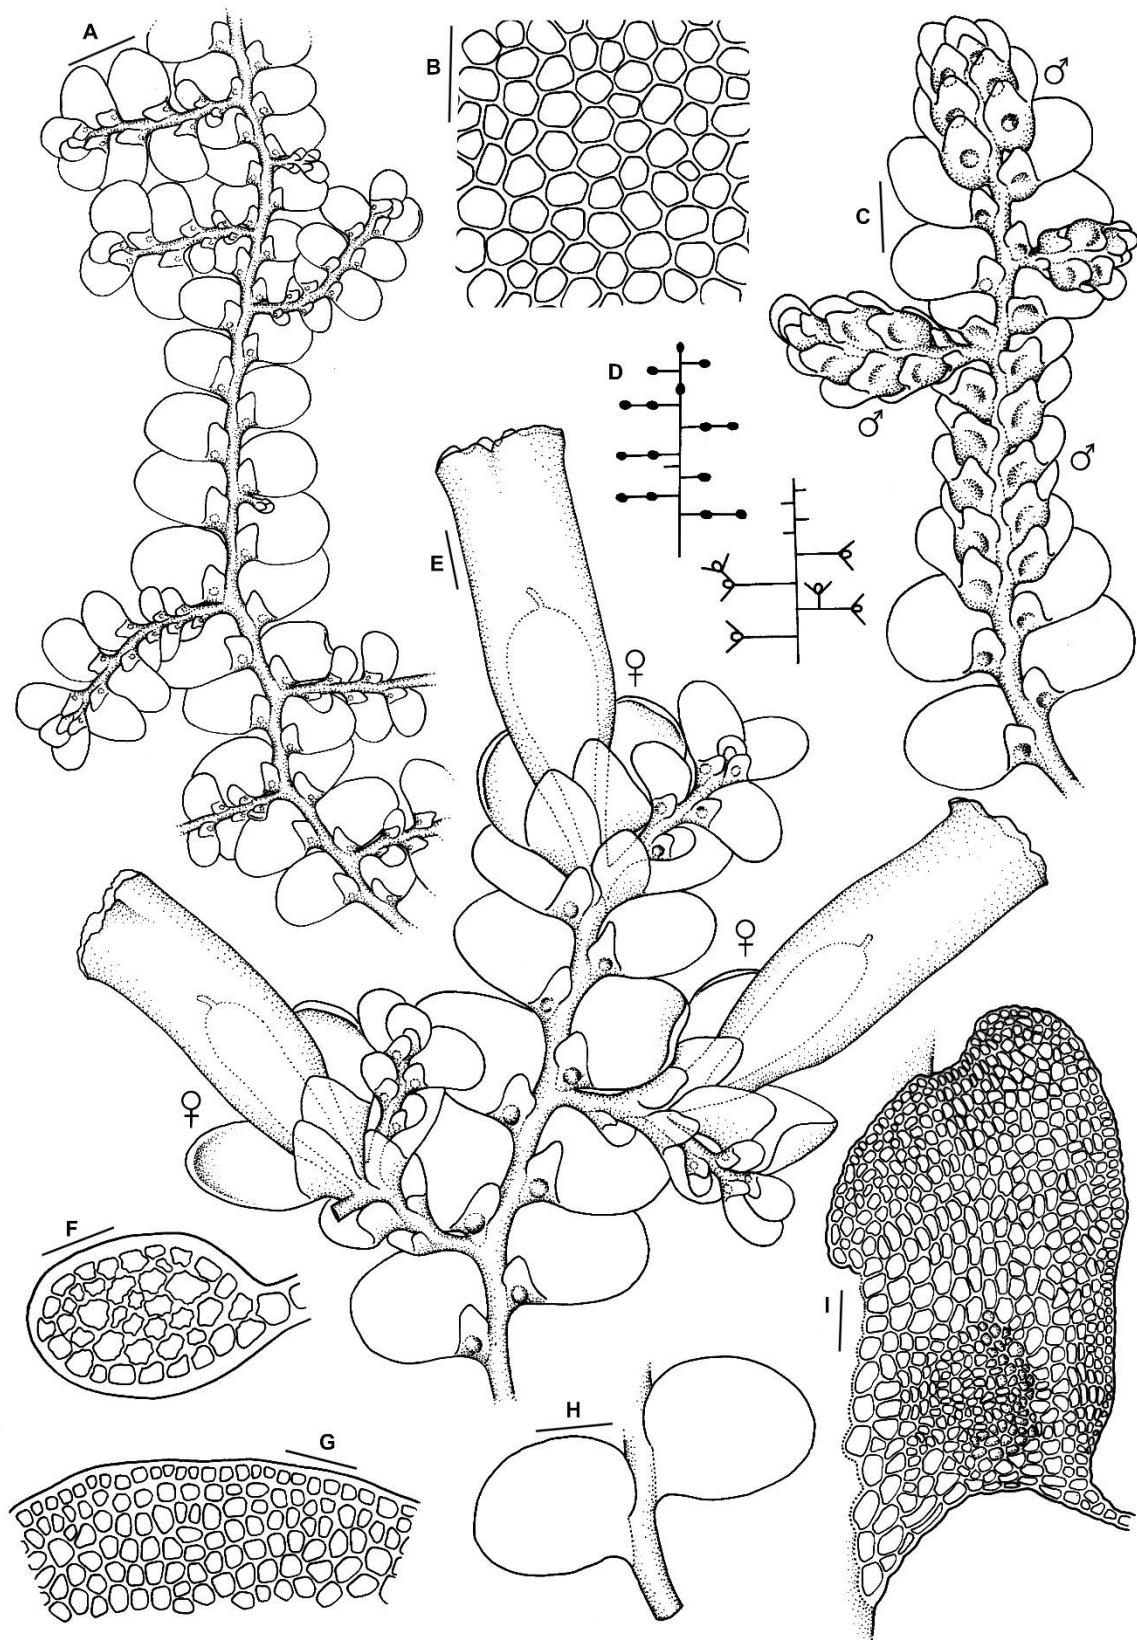

Figure 14. A-I. *Radula ligula* - A. Habit. B. Median leaf cells. C. Habit with androecia. D. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). E. Habit with gynoecia. F. Cross section of a stem. G. Marginal leaf cells. H. Leaf, dorsal view. I. Lobule. (A= 1000 µm; B, F, G, I= 50 µm; C, E, H= 500 µm; A, B, F-I from the holotype; C-E from ICN39132).

1.3 mm long, 0.7–1 mm wide, dorsal base rounded, not overlapping the stem, apex rounded, margin plane, entire; marginal cells quadrate, 5–12 µm in diam., median cells isodiametric, 12–25 µm in diam., basal cells isodiametric to elongate, 20–35 × 12–20 µm, cell walls thick, trigones small to lacking, cuticle smooth. LOBULES distant, ligulate, 0.25–0.7 mm long, 0.15–0.3 mm wide, ca. 1/4 of the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded, covering 1/5 the stem, free margin plane, rounded, arching towards base, apex plane, rounded to obtuse, distal margin straight to rounded; keel concave, spreading at angles of 70–80° with the stem, lobules. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on short branches, with 2–4 pairs of bracts, 0.55–1 mm wide; bracts distant to imbricate, ovate, 0.45–0.9 mm long, 0.35–0.55 mm wide, apex rounded, margin plane or recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex obtuse. GYNOECIA on short branches, with 1–2 innovations, innovations usually rudimentary; bracts oblong-ovate, 1.6–1.7 mm long, 0.6–0.7 mm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2.5–4 mm long, 0.7–1.1 mm wide at apex, mouth entire. VEGETATIVE REPRODUCTION not observed.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1962, p. 147–148, Fig. 3), Yamada (1981, p. 388–389, Fig. 13, 2003, Fig. 82A), Reiner-Drehwald (1994, p. 12–14, Fig. 3D–E).

DISTRIBUTION AND HABITAT: Brazil and Argentina (Reiner-Drehwald 1994). In Brazil known from Bahia, Minas Gerais, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. The species usually grows in humid rainforest, preferably near water bodies, on rock, tree trunks or decaying wood, at 30–1750 m elevation.

TAXONOMIC NOTES: *Radula ligula* is readily identified by (1) leaf lobes bordered by 3–4 rows of quadrate thick-walled cells; (2) lobules ligulate (parallel to the stem) with rounded apex; keel concave and inflated only at rhizoid area. These characters are unparalleled among *Radula* species in Brazil.

SELECTED EXAMINED SPECIMENS: **BRAZIL.** BAHIA: Uruçuca, 6,2 km N of town of Serra Grande, ca. 40 km N of Ilhéus along coast, ca. 200 m, 14°26'S, 39°03'W, 200 m, 17 July 1991, Vital & Buck 20271 (NY). Fig. 15

TYPE: Cuba, Santiago, Sierra de la Gran Piedra, near Finca Isabella, 1100 m, Pócs 9128/AR (isotype: NICH-400981!).

Dioicous. PLANTS 1.3–1.9 mm wide, yellowish-green in herbarium, irregularly pinnate to dichotomous. STEMS in cross section with ca. 14 thick-walled epidermal cells surrounding ca. 14 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls yellowish, trigones lacking. LEAVES widely spreading, imbricate, slightly convex, oblong to oblong-falcate, 0.6–0.95 mm long, 0.4–0.7 mm wide, dorsal base rounded, not overlapping the stem, apex obtuse to subacute, margin plane, entire; marginal cells subquadrate to isodiametric, 10–15 × 8–12 µm, median and basal cells isodiametric to elongate, 20–25 × 15–20 µm, cell walls thin, trigones small to lacking, cuticle smooth. LOBULES distant, subquadrate, 0.2–0.3 mm long, 0.15–0.2 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line straight to slightly arched, base plane to recurved, rounded, covering up to 1/3 the stem, free margin plane to slightly recurved, straight to sinuate, apex rounded to subacute, distal margin straight; keel straight, rarely slightly convex, spreading at angles of 50–60° with the stem. RHIZOIDS brownish, scanty. ANDROECIA not seen. GYNOECIA on long branches, with two innovation; bracts oblong-ovate, 0.75–0.85 mm long, 0.4–0.5 mm wide, apex rounded to obtuse, margin plane, entire, lobule oblong, ca. 1/2 the lobe length, apex obtuse to subacute. PERIANTHS and VEGETATIVE REPRODUCTION not seen.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1983, p. 243–245, Fig. 2).

DISTRIBUTION AND HABITAT: Cuba and Brazil. New to Brazil, from Rio Grande do Sul, where it grows on tree trunks in Atlantic forest.

TAXONOMIC NOTES: *Radula longiloba* is characterized by (1) stems slender with ca. 14 thick-walled epidermal cells surrounding ca. 14 thin-walled medullary cells; (2) leaves oblong to oblong-falcate with obtuse to subacute apex; (3) leaf cells with trigones small or lacking; (4) lobules distant, subquadrate with rounded base, covering up to 1/3 the stem, free margin straight to sinuate, and keel usually straight, rarely slightly convex, inflated at rhizoid area.

Radula longiloba shares similarities with *R. mexicana* and *R. pseudostachya*, but *R. mexicana* is autoicous and has ovate leaves with a rounded to obtuse apex, while *R. pseudostachya*

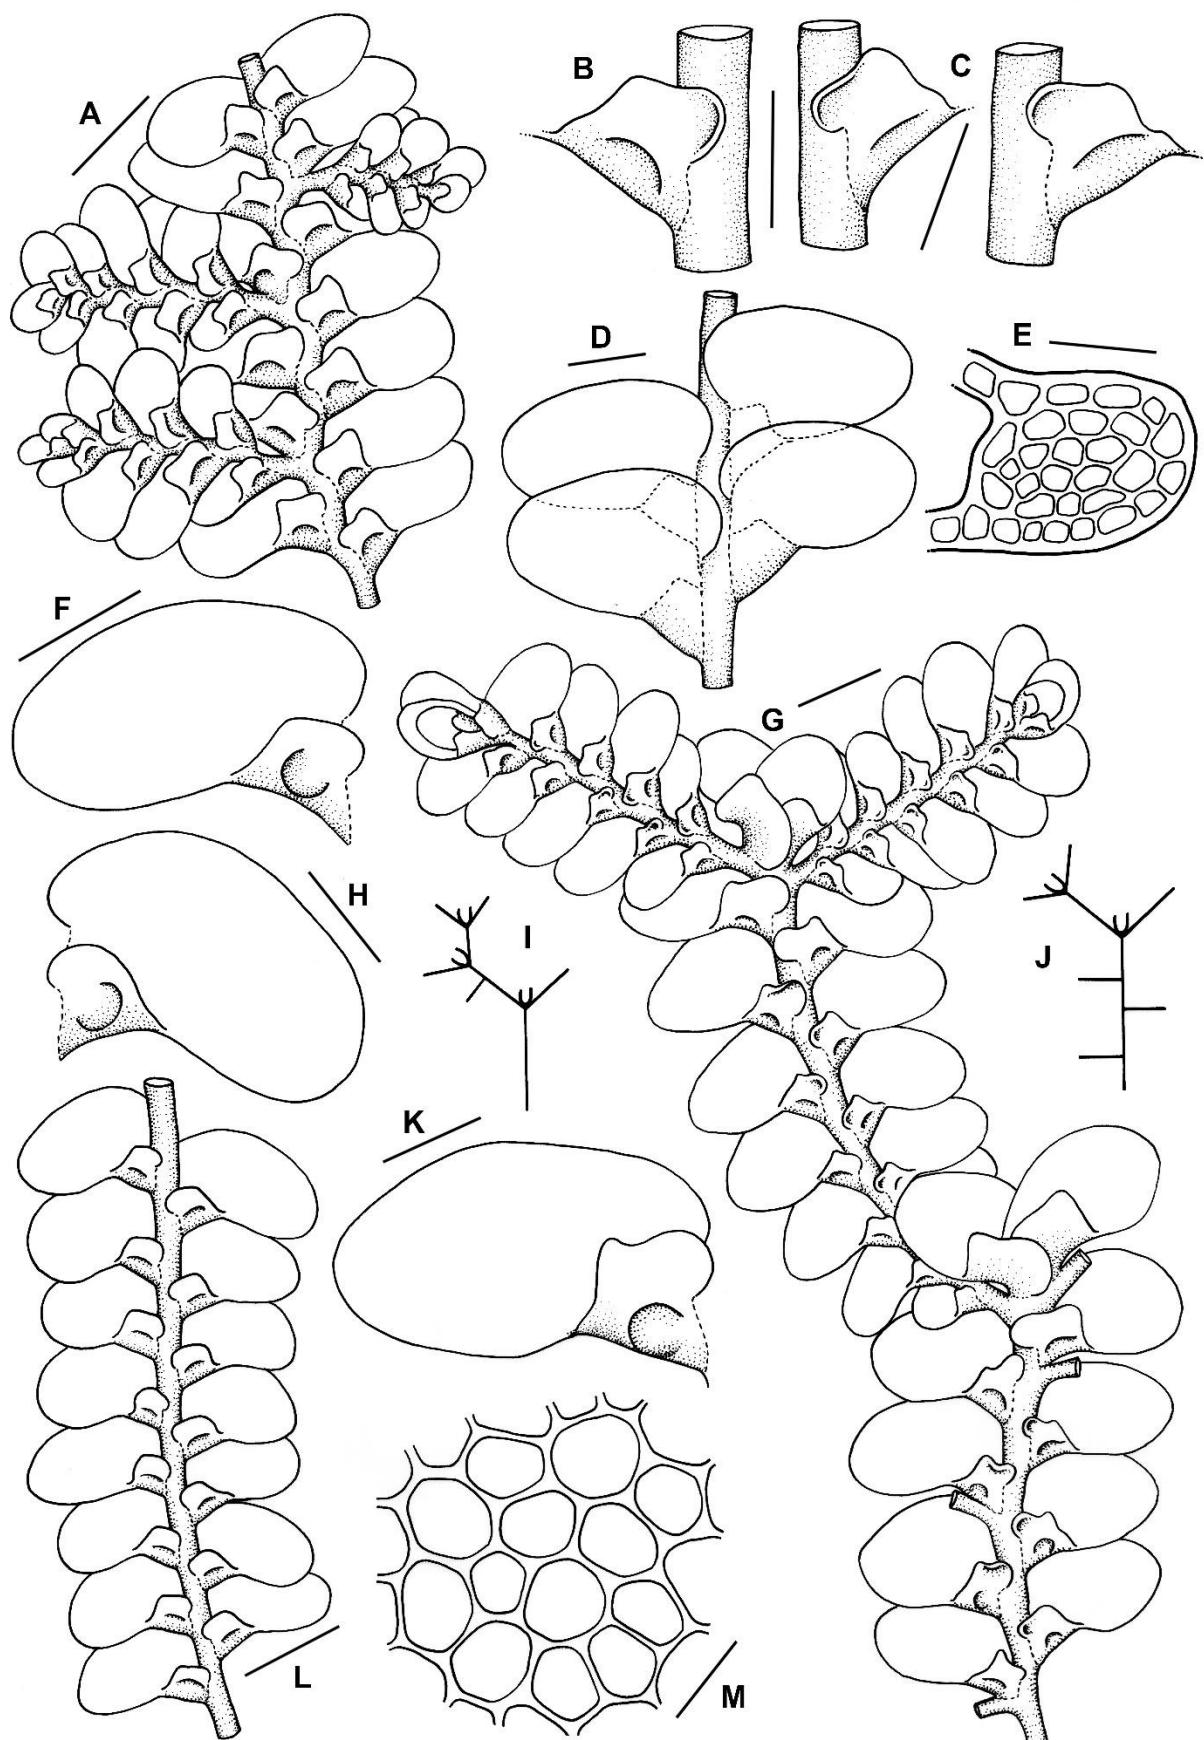

Figure 15. A-M. *Radula longiloba* – A, G, L. Habit. B-C. Lobules. D. Habit, dorsal view. E. Cross section of a stem. F, H, K. Leaves. I-J. Cladograph of plants. M. Median leaf cells (A, G, L= 500 μm ; B-D, F, H, K= 250 μm ; E= 50 μm ; M= 25 μm ; A, K from holotype NICH; B-J, L-M from SP182102).

has lobules contiguous to subimbricate with the base covering at least 1/2 the stem, and cells with large trigones and verruculose cuticle (Yamada, 1983).

Radula longiloba is closely related to *R. yamadae* but differs from the latter mainly by leaves oblong and falcate, lobules distant, 1/3–1/2 the leaf length, lobule base covering up to 1/3 the stem, and keel straight to slightly convex. In *R. yamadae*, leaves are ovate and widely spreading but not falcate, lobules are distant to contiguous, rarely imbricate, 1/2–2/5 the lobe length, with lobule base covering 1/3 to fully overlapping the stem, and the keel is conspicuously convex (Oliveira-da-Silva & Ilku-Borges 2020).

EXAMINED SPECIMEN: **Brazil.** RIO GRANDE DO SUL: Cambará do Sul, Parque Nacional de Aparados da Serra, sobre tronco vivo, estrada para o hotel, 27 April 1983, Yano & Pirani 7028 (SP).

Radula mammosa Spruce, Mem. Torrey Club 1: 127. 1890.

Fig. 16

TYPE: Bolivia, Yungas, “in Acrostichi frondibus cum Lejeuneis repens,” 4000 ft., 1885, Rusby 3025 p.p. (isotypes: NY-01021130!, G-00265038!).

Dioicous. PLANTS 1–1.6 mm wide, yellowish-green to pale green in herbarium, irregularly pinnate. STEMS in cross section with ca. 13 thin-walled epidermal cells surrounding ca. 9 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls yellowish to colorless, trigones lacking. LEAVES widely spreading, contiguous to shallowly imbricate, plane to slightly convex, ovate to falcate-ovate, 0.7–0.95 mm long, 0.4–0.7 mm wide, dorsal base rounded, not overlapping the stem, apex rounded, margin plane, entire; marginal cells subquadrate to isodiametric, 12–15 × 10–12 µm, median and basal cells isodiametric to elongate, 22–25 × 12–17 µm, cell walls thin, trigones lacking, cuticle smooth. LOBULES distant, subquadrate, 0.25–0.45 mm long, 0.2–0.35 mm wide, 1/3–1/2 the lobe length, strongly inflated at rhizoid area, insertion line straight to slightly arched, base plane, straight, not covering the stem, free margin plane, straight, apex plane, rounded, distal margin straight; keel strongly convex, rarely slightly straight on branches, spreading at angles ca. 60° with the stem. RHIZOIDS colorless to brown, numerous on a pronounced mammiliform swelling. ANDROECIA not seen. GYNOECIA on stems, with two innovations; bracts oblong-ovate, 0.9–1 mm long, 0.45–0.5 mm wide, apex rounded, margin plane, entire, lobule ca. 1/2 of lobe length, oblong, apex rounded to obtuse. PERIANTHS subcylindrical, 2.4–2.6 mm long, 0.45–0.8 mm wide at apex, mouth entire, undulate. VEGETATIVE REPRODUCTION not observed.

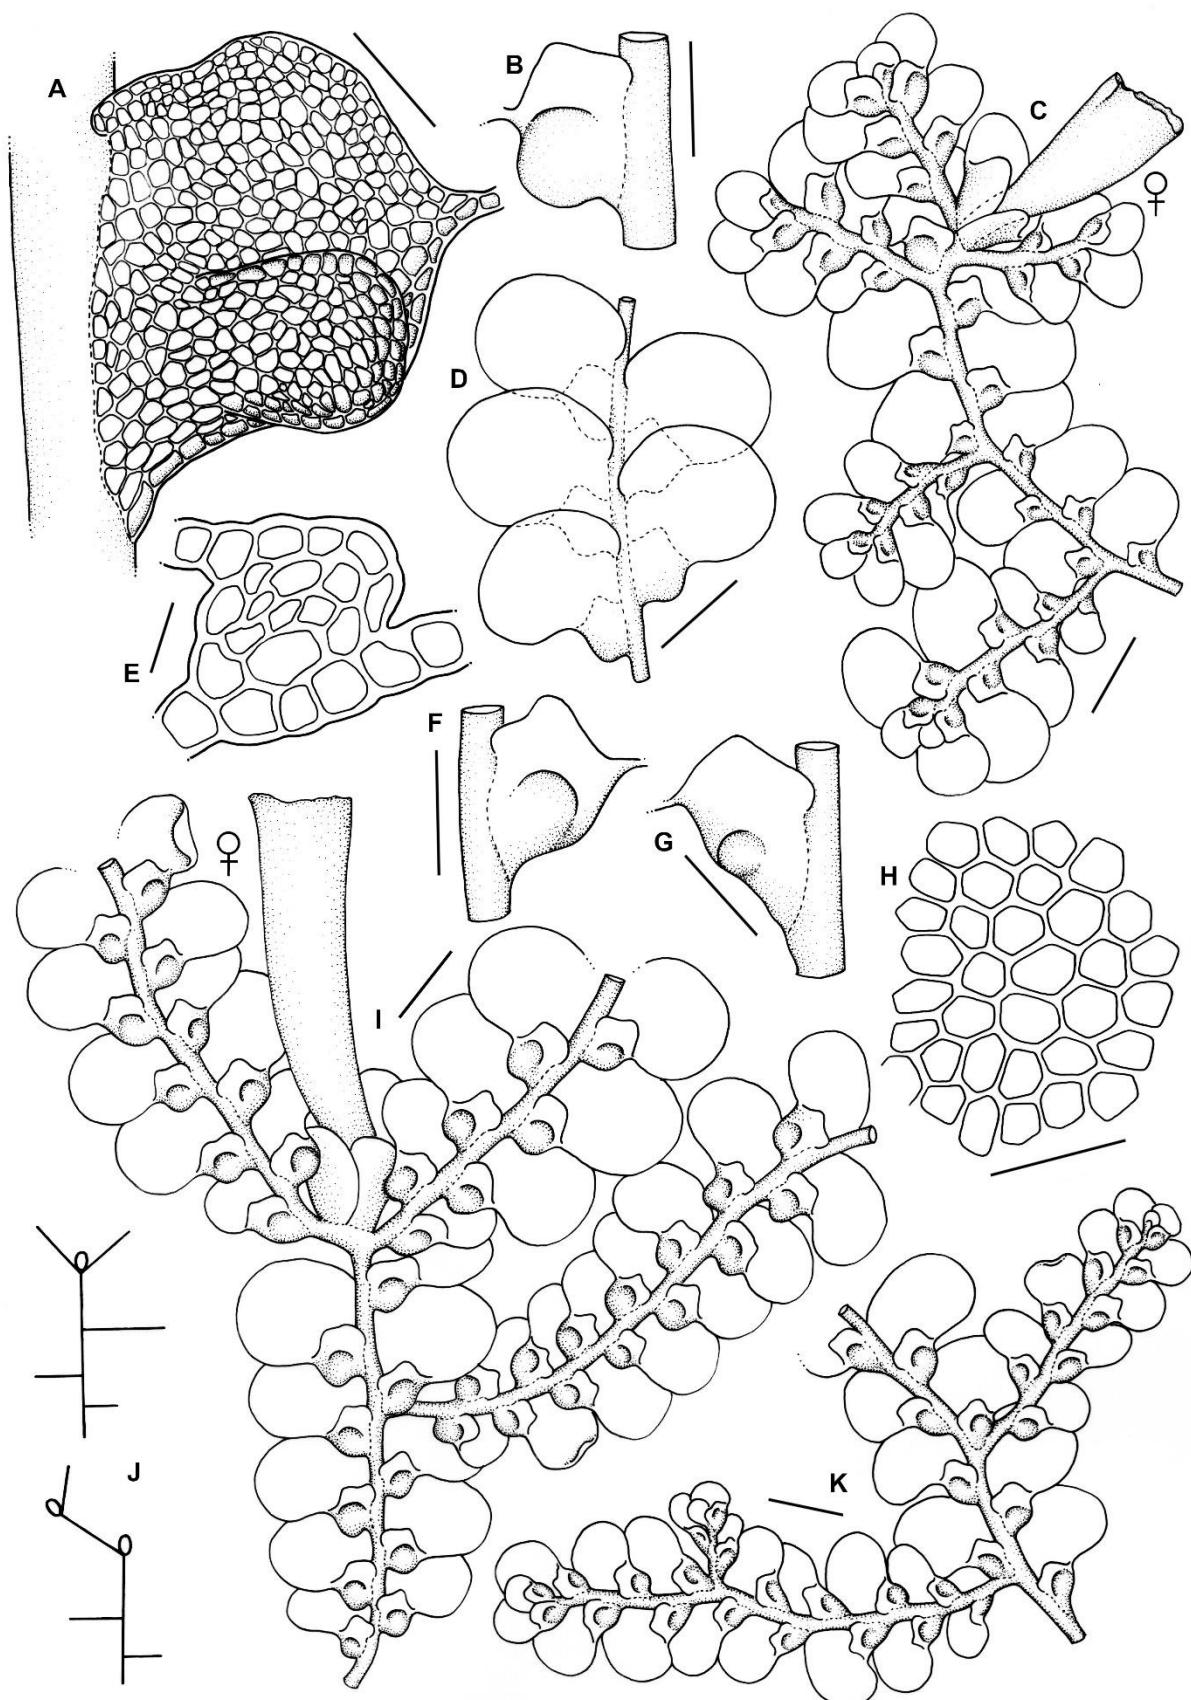

Figure 16. A-K. *Radula mammosa* - A-B, F, G. Lobule. C, I. Habit with gynoecia. D. Habit, dorsal view. E. Cross section of a stem. H. Median leaf cells. J. Cladograph of fertile plants (open ellipse= gynoecia with perianth). K. Habit. (A= 100 μm ; B, F, G= 250 μm ; C, D, I, K= 500 μm ; E= 25 μm ; H= 50 μm ; A-B, D-J from Isotype G00265038; C, K from SP452187).

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1939, p. 24–26, Fig. 2), Yamada (1993a, p. 130–131, Fig. 50 based on the holotype of *R. verrucifolia*, 2003, Fig. 83E).

DISTRIBUTION AND HABITAT: Tropical America. In Brazil recorded from Pará, Paraná, Rio de Janeiro and São Paulo. The species usually occurs on living leaves, occasionally on bark or rock, at 500–1800 m elevation.

TAXONOMIC NOTES: *Radula mammosa* is characterized by (1) plants small, usually epiphyllous (occasionally occurring on bark or rock); (2) leaves ovate to falcate-ovate; (3) leaf cells without trigones; (4) lobule base straight, not covering the stem, keel strongly convex (rarely almost straight on branches), and with a pronounced mammiliform swelling at the rhizoid area; (5) gemmae absent.

This species resembles *R. flaccida* and *R. stenocalyx* by the epiphyllous plants with lobules strongly inflated at the rhizoid area. However, *R. mammosa* differs from the latter two species by the absence of gemmae and, additionally, from *R. flaccida* by the lobule base not covering the stem and lobule apex rounded (covering 1/5–1/4 the stem and lobule apex extended towards an obtuse tip in *R. flaccida*), and from *R. stenocalyx* by the subcylindrical perianth, 2.4–2.6 mm long and 0.45–0.8 mm wide at apex (trumpet-shaped to subcylindrical, 1.5–2 mm long and 0.2–0.3 mm wide at apex in *R. stenocalyx*). *Radula mammosa* also resembles *R. yamadae* but differs from the latter by leaf lobes with apex rounded and lobule base straight, not covering the stem. In *R. yamadae*, leaf apex is obtuse to subacute and the lobule base covers 1/3 to fully overlaps the stem (Oliveira-da-Silva & Ilku-Borges 2020).

SELECTED EXAMINED SPECIMENS: **BRAZIL.** PARÁ: São Geraldo do Araguaia, Serra dos Martírios-Andorinhas, Fazenda Andorinhas, 6°10'2,8"S, 48°26'30,2"W, 18 December 2007, Lisboa & Barros 5703 (MG). Monoicous. PLANTS 1.5–2 mm wide, yellowish-green to yellowish-brown in herbarium, irregularly pinnate. STEMS in cross section with ca. 23 thick-walled epidermal cells surrounding ca. 25 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls yellowish, medullary cell walls colorless, trigones small. LEAVES obliquely to widely spreading, imbricate, slightly convex, ovate, 0.8–1.3 mm long, 0.6–0.9 mm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin plane to incurved, entire; marginal cells subquadrate to isodiametric, 10–15 × 8–10 µm, median and basal cells isodiametric to elongate, 15–20(–25) × 10–15 µm, cell walls thin, trigones small to lacking, cuticle smooth. LOBULES distant, (sub)quadrate, 0.3–0.6 mm long, 0.2–0.45 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line ± straight, base plane, rounded, covering up to 1/3 (rarely 1/2) the stem, free margin plane, straight, apex plane, rounded to acute, rarely obtuse, distal margin straight; keel straight, spreading at angles of 40–50° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal on short branches, with 1–5 pairs of bracts, 0.7–1 mm wide; bracts distant to imbricate, ovate, 0.7–0.9 mm long, 0.3–0.4 mm wide, apex rounded, margin plane, entire, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex rounded. GYNOECIA on short branches, with 1–2 innovations; bracts ovate, 1–1.1 mm long, 0.5–0.6 mm wide, apex rounded, margin plane to incurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded. PERIANTHS subcylindrical, 2–3 mm long, 0.6–0.8 mm wide at apex, mouth entire to slightly irregularly undulate. VEGETATIVE REPRODUCTION by stem fragmentation.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1964, p. 192–194, Fig. 3), Yamada (1993a, p. 131–133, Fig. 51 based on the holotype of *R. cordovana*).

DISTRIBUTION AND HABITAT: Tropical and subtropical America. In Brazil, it occurs in Espírito Santo, Pernambuco and Rio Grande do Sul. This is an uncommon species that grows on tree trunks and decaying wood in Atlantic forest.

TAXONOMIC NOTES: *Radula mexicana* is characterized by (1) plants monoicous; (2) lobules distant, (sub)quadrate, base rounded, covering up to 1/3 (rarely 1/2) the stem, apex rounded to acute, rarely obtuse, keel straight.

Radula mexicana resembles *Radula angulata* in the lobule apex and leaf shape, but differs from the latter by lobule base covering up to 1/3 (rarely 1/2) the stem (covering 1/2 to fully overlapping the stem in *R. angulata*), plants monoicous (dioicous in *R. angulata*), and leaf cells without trigones (trigones small at leaf base and increasing in size towards the margin in *R. angulata*). *Radula mexicana* was long considered the only monoicous *Radula* species in Brazil but in this study, two further monoicous taxa were detected, *R. fendleri* var. *paroica* and *R. renneri*.

SELECTED EXAMINED SPECIMENS: **Brazil.** ESPÍRITO SANTO: Itapecoá, Iconha, Est. do Espírito Santo, 18 April 1965, Vital 376 (SP). PERNAMBUCO: Caruaru, Brejo dos Cavalos, 18 August 1987, Pôrto 2046h (UFP). RIO GRANDE DO SUL: Torres, 08 July 1977, Vianna 3287 (ICN).

Dioicous. PLANTS 1.9–2.5 (–3) mm wide, yellowish-brown to reddish-brown in herbarium, regularly pinnate. STEMS in cross section with ca. 40 thick-walled epidermal cells surrounding ca. 71 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls colorless, trigones lacking. LEAVES widely spreading, distant to contiguous, convex, ovate, 0.9–1.2 (–1.5) mm long, 0.7–1 (–1.2) mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane to slightly recurved, entire; marginal cells subquadrate to rounded, 15–20 × 10–15 µm, median and basal cells isodiametric, 20–25 × 15–20 µm, cell walls thin, trigones small, cuticle smooth. LOBULES distant, (sub)quadrate, 0.5–0.7 mm long, 0.3–0.5 mm wide, 1/3–1/2 the lobe length, inflated along the keel and at rhizoid area, insertion line straight, base plane, rounded, covering up to 1/2 the stem, free margin sinuate-plicate in the middle, apex plane to incurved, rounded, distal margin sinuate; keel straight to convex, spreading at angles of 40–50° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal to intercalary on long branches, with 2–6 pairs of bracts, 0.9–1.1 mm wide; bracts ovate, 0.7–0.8 mm long, 0.2–0.25 mm wide, apex rounded, margin recurved, entire, lobule ovate, ca. 5/6 of lobe length, base rounded, free margin straight, apex rounded to ± obtuse. GYNOECIA on long branches, with two innovations; bracts oblong-ovate, 0.9–1 mm long, 0.6–0.7 mm wide, apex rounded to obtuse, margin plane to ± recurved, entire, lobules ca. 1/2 of lobe length, oblong, apex rounded. PERIANTHS subcylindrical, 2–2.8 mm long, 0.7–1.1 mm wide at apex, mouth irregularly undulate. VEGETATIVE REPRODUCTION not observed.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1967, p. 33–35, Fig. 13), Jans (1979, p. 425–426, Fig. 1i), Yamada (1982, p. 458–461, Figs. 28–29, 2003, Fig. 84D), Bouman & Dirkse (1990, p. 122–123, Fig. 3).

DISTRIBUTION AND HABITAT: Costa Rica, Ecuador, Colombia, Bolivia, Brazil and Macaronesia (Azores and Madeira). In Brazil known from Espírito Santo, Minas Gerais, Paraná, Pernambuco,

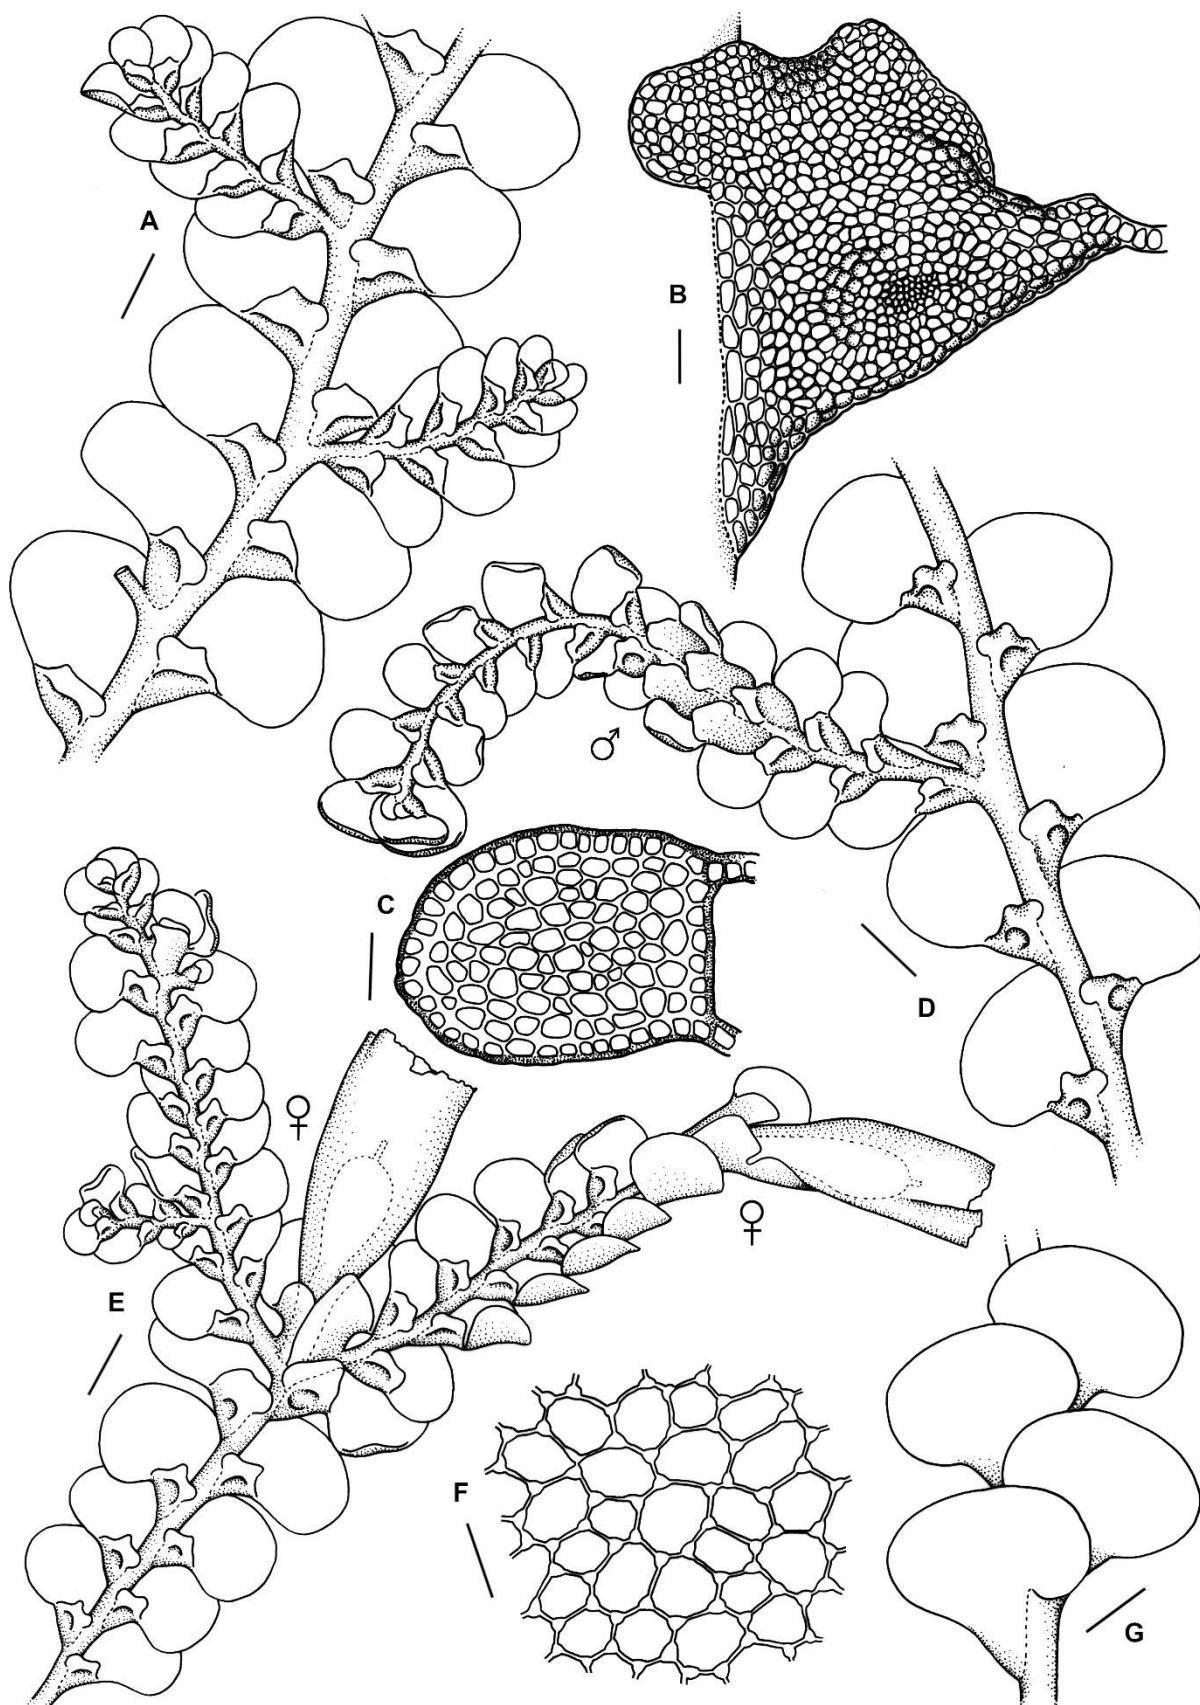

Figure 18. A-G. *Radula nudicaulis*. A. Habit. B. Lobule. C. Cross section of a stem. D. Habit with androecia. E. Habit with gynoecia. F. Median leaf cells. G. Habit, dorsal view (A, D, E, F= 500 μm ; B, C=50 μm ; F=25 μm ; A, C, G from holotype G00043871; B, D, E, F from RB284180).

Rio de Janeiro, Rio Grande do Sul, Rondônia, Roraima, Santa Catarina and São Paulo. The species grows on trunks of living trees, decaying wood and rock, in humid places at 125–2020 m elevation.

TAXONOMIC NOTES: *Radula nudicaulis* is characterized by (1) plants regularly pinnate; (2) leaves distant to contiguous, convex, ovate; (3) lobules distant, (sub)quadrate, base rounded, covering up to 1/2 the stem, free margin usually sinuate-plicate in the middle, keel straight to convex, spreading at angles of 40–50° with the stem.

Radula nudicaulis resembles *R. pallens* in lobule shape, but the latter differs by irregularly pinnate to dichotomous branching, leaves imbricate, and keel straight to concave, spreading at angles of 60–70° with the stem.

Dioicous. PLANTS 1.5–3 mm wide, olive-green to brown in herbarium, irregularly pinnate to dichotomous. STEMS in cross section with ca. 35 thick-walled epidermal cells surrounding ca. 68 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones small to lacking. LEAVES widely spreading, imbricate, slightly convex, suborbicular, 1.1–1.6 mm long, 0.8–1.1 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane, entire; marginal cells subquadrate to isodiametric, 15–20 × 10–15 µm, median and basal cells isodiametric, 15–20 µm, cell walls thin, trigones small to usually lacking, cuticle smooth. LOBULES distant, (sub)quadrate, 0.3–0.6 mm long, 0.2–0.5 mm wide, 1/4–1/3 the lobe length, inflated at rhizoid area, insertion line straight, base plane to recurved, rounded, covering 1/2 the stem, rarely fully overlapping the stem on branches, free margin plane, ± straight, apex plane to sometimes incurved, rounded to ± obtuse, distal margin straight; keel straight to concave, spreading at angles of 60–70° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA terminal to intercalary on long branches, with 3–6 pairs of bracts, 0.9–1.4 mm wide; bracts distant to subimbricate, ovate, 0.8–1 mm long, 0.3–0.6 mm wide, apex rounded, margin plane to rarely recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded to obtuse, free margin ± straight, apex rounded. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 1–1.3 mm long, 0.5–0.8 mm wide, apex rounded, margin plane, entire, lobule oblong, 1/2–1/3 of lobe length, apex rounded. PERIANTHS subcylindrical, 2.3–4 mm long, 1–1.4 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by regenerants on leaf margins and leaf surfaces, caducous *Lejeunea*-type branches and stem fragmentation.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1959a, p. 39–42, Fig. 18 as *R. kegelii*, 1960, 1967, p. 30–32, Fig. 12), Yamada (1980, p. 248–250, Fig. 5 as *R. kegelii*), Reiner-Drehwald (1994, p. 10–12, Fig. 2B as *R. kegelii*), Lemos-Michel (2001, p. 157–159, Fig. 44 as *R. kegelii*), Gradstein & Ilku-Borges (2009, p. 40–41, Fig. 22I–K as *R. kegelii*).

DISTRIBUTION AND HABITAT: Widespread in tropical America. In Brazil recorded from Acre, Alagoas, Amazonas, Bahia, Espírito Santo, Mato Grosso, Minas Gerais, Pará, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. The species usually grows on bark and decaying wood, from sea level to 1560 m elevation.

TAXONOMIC NOTES: *Radula pallens* is characterized by (1) plants irregularly pinnate to dichotomous; (2) leaves suborbicular with entire margins and broadly rounded apex; (3) leaf cells small, 15–20 µm in midleaf, thin-walled, trigones small or lacking, cuticle smooth; (4) lobules distant, parallel to stem, (sub)quadrate, base rounded, covering up to 1/2 the stem (rarely fully overlapping the stem on branches), apex rounded to obtuse, keel straight to concave.

The species was considered endemic to Jamaica by Castle (1960), but Gradstein (in press) based on study of the types found that it is conspecific with *R. kegelii*, a species widely distributed in the Neotropics. *Radula pallens* is also conspecific with *R. obovata*, a species recorded from Mexico, West Indies (Castle 1959a) and Brazil (Yamada 2003).

Fig. 20

TYPE: Cuba, Santiago, Sierra de la Gran Piedra, Finca Isabelica, 1100 m, 30 October 1980, Pócs & Caduf 9199/AQ (isotype: NICH-400982!).

Dioicous. PLANTS 1.5–2 mm wide, green to yellowish-green in herbarium, dichotomous. STEMS in cross section with ca. 17 thick-walled epidermal cells surrounding ca. 18 thick-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls brown, trigones large. LEAVES widely spreading, distant to contiguous, convex, ovate to falcate-ovate, 0.9–1.2 mm long, 0.6–0.9 mm wide, dorsal base rounded, not overlapping the stem, apex rounded, margin plane, entire; marginal cells subquadrate, 10–12 × 8–10 µm, median and basal cells isodiametric to elongate, 20–35 × 15–20 µm, cell walls thin, trigones small at leaf base, increasing

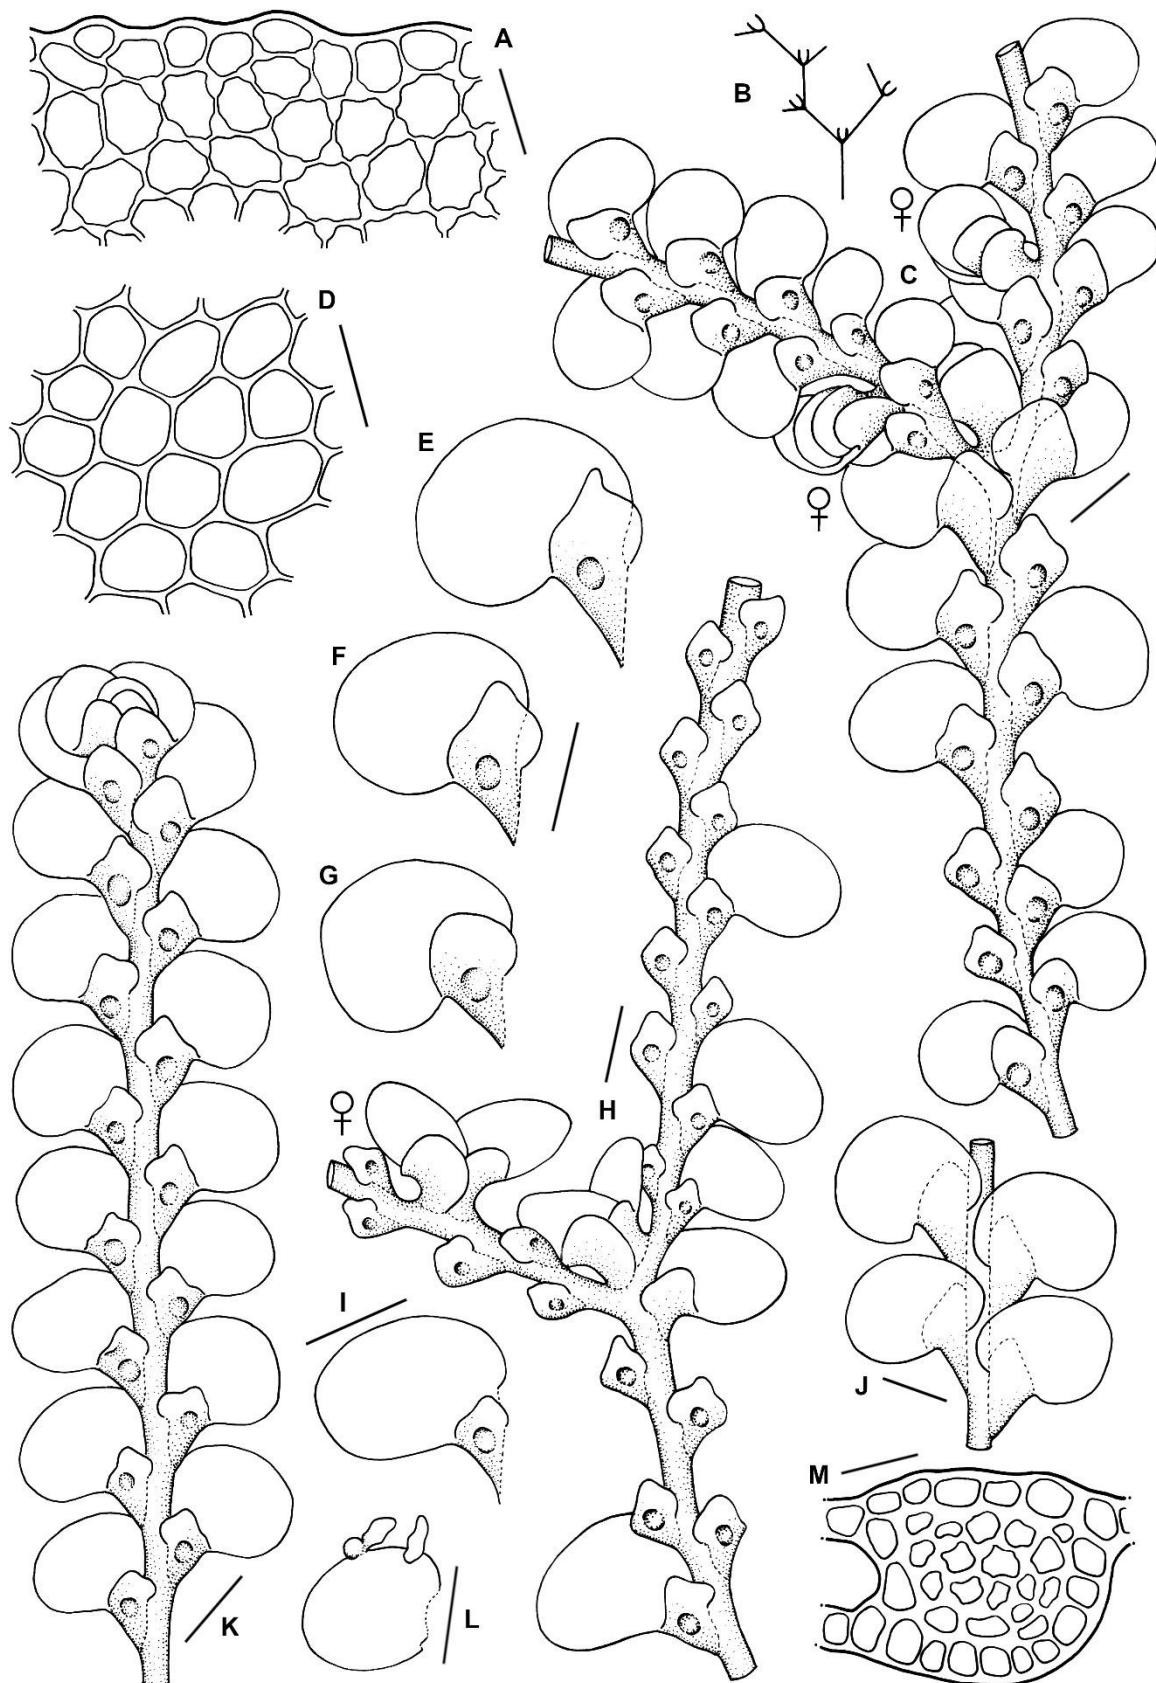

Figure 20. A-M. *Radula pocsii* - A. Marginal leaf cells. B. Cladograph of plants (U= gynoecia without perianth). C, H, K. Habit, ventral view. D. Median leaf cells. E-G, I. Leaves. J. Habit, dorsal view. L. Leaf with regenerants. M. Cross section of a stem. (A, D= 25 μm ; C, E-L= 500 μm ; M= 50 μm ; A, D, K from SP452239; B-C, E-J, L-M from isotype NICH400982).

in size towards the margins, cuticle smooth. LOBULES distant, rhombic, 0.5–0.8 mm long, 0.25–0.5 mm wide, 1/3–1/2 the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded, covering 1/3–1/2 the stem, free margin plane, straight, apex plane, rounded to obtuse, distal margin straight to slightly sinuate; keel straight, spreading at angles of 30–40° with the stem. RHIZOIDS not seen. ANDROECIA not seen. GYNOECIA on long branches, with 1–2 innovations; bracts ovate to oblong, 0.8–1 mm long, 0.4–0.65 mm wide, apex rounded to obtuse, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS not seen. VEGETATIVE REPRODUCTION by caducous leaf lobes and regenerants.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1983, p. 245–247, Fig. 3).

DISTRIBUTION AND HABITAT: Cuba and Brazil. In Brazil recorded from Paraná, Rio de Janeiro, Rio Grande do Sul and São Paulo. The species grows in Atlantic forest on tree trunks and rock, usually in humid places, at 650–1700 m elevation.

TAXONOMIC NOTES: *Radula pocsii* is characterized by (1) plants dichotomous; (2) leaves distant to contiguous, convex, ovate to usually falcate-ovate; (3) leaf cells with trigones small at leaf base increasing in size towards the margins; (4) lobules distant, rhombic, with base rounded, covering 1/3–1/2 the stem, apex rounded, keel straight (long), spreading at angles of 30–40° with the stem, lobule inflated at rhizoid area.

The species resembles *R. javanica* but the latter species is irregularly pinnate (dichotomous in *R. pocsii*), without or with small trigones, which do not increase in size towards the leaf margin (increasing in size towards the margins in *R. pocsii*), and lobules 0.2–0.45 × 0.1–0.25 mm (0.5–0.8 × 0.25–0.5 mm in *R. pocsii*).

SELECTED EXAMINED SPECIMENS: **BRAZIL.** PARANÁ: Morretes, Parque Estadual do Marumbi, trilha vermelha, 25°26'55"S, 48°54'54"W, 1200 m, 22 July 2014, Peralta et al. 15804 (SP). medullary cells, epidermal and medullary cells of the same size, cell walls yellowish to brown, trigones large. LEAVES widely spreading, contiguous to subimbricate, convex, falcate-ovate, 0.8–1.1 mm long, 0.5–0.7 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin recurved, entire; marginal cells subquadrate, 10–15 × 5–10 µm, median cells isodiametric, 15–30 µm in diam., basal cells elongate, 30–35 × 15–25 µm, cell walls thin, trigones large, cuticle verruculose. LOBULES contiguous to subimbricate, subquadrate to subrectangular, 0.4–0.6 mm long, 0.25–0.4 mm wide, ca. 1/2 the lobe length, strongly inflated along the keel, insertion line arched, base plane, rounded, covering 1/2 to fully overlapping the stem, free margin plane, straight, apex plane, rounded, distal margin straight; keel convex, spreading at angles of 50–60° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA not seen. GYNOECIA on short branches, with 2 innovations; bracts ovate, 0.6–0.8 mm long, 0.3–0.45 mm wide, margin entire, plane to ± recurved, apex rounded, lobule oblong, ca. 1/2 of lobe length, apex obtuse. PERIANTHS not seen. VEGETATIVE REPRODUCTION by caducous leaf lobes, producing almost completely naked branches.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1967, p. 21–22, Fig. 8), Yamada (1980, p. 251–252, Fig. 7).

DISTRIBUTION AND HABITAT: Venezuela and Brazil. In Brazil only known from Amazonas, where it was found growing on bark. The type is from Venezuela, not from Brazil (Castle 1967, Yamada 1980).

TAXONOMIC NOTES: *Radula pseudostachya* is characterized by (1) plants with strongly caducous leaf lobes, branches often almost denuded; (2) leaves falcate-ovate, convex with strongly recurved margins; (3) cell with large trigones and verruculose cuticle; (4) lobules contiguous to subimbricate, subquadrate to subrectangular, base covering 1/2 to fully overlapping the stem, keel convex, strongly inflated along the keel.

This species is closely related to *R. fendleri* var. *fendleri*; for differences see under the latter.

SELECTED EXAMINED SPECIMENS: **Brazil.** AMAZONAS: Manaus, Manaus-Caracarai road, km 45, caatinga on white sand, on tree trunk, 5 April 1971, Prance et al. 11384 (INPA).

Radula punctata Steph., Hedwigia 23: 135. 1884.

Fig. 22

TYPE: Chile, Krause s.n., ex hb. Sande Lacoste (holotype: G-00112207!).

= *Radula plumosa* Steph., Hedwigia 23: 154. 1884, fide Castle (1937 “1936”).

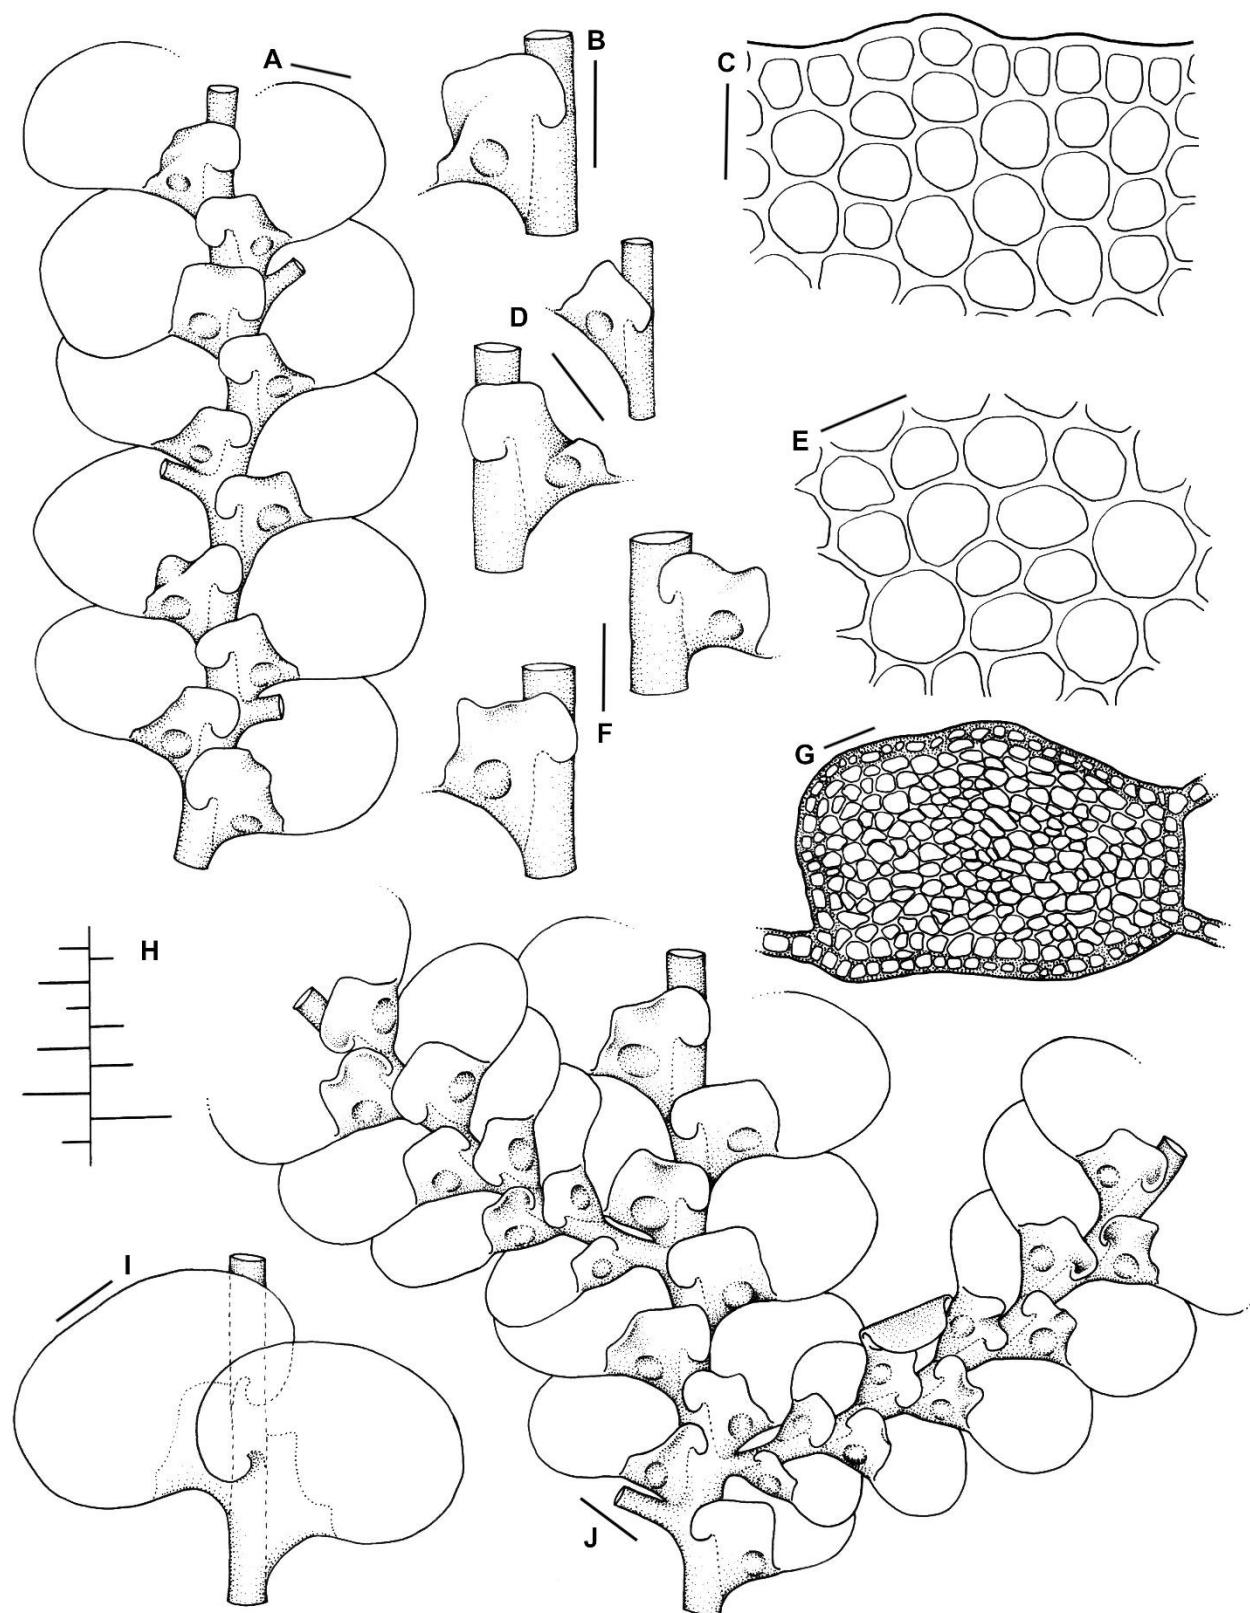

Figure 22. *A-J. Radula punctata* - A, J. Habit. B, D, F. Lobules. C. Marginal leaf cells. E. Median leaf cells. G. Cross section of a stem. H. Cladograph of plants. I. Leaf dorsal view. (A, B, D, F, I, J= 500 µm; C, E= 25 µm; G= 50 µm; A-J from RB629672).

Dioicous. PLANTS 2–3.2 mm wide, green to brown in herbarium, regularly pinnate. STEMS in cross section with ca. 60 thick-walled epidermal cells surrounding ca. 200 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones small to lacking. LEAVES widely spreading, shallowly imbricate, slightly convex, ovate, 1–1.5 mm long, 0.7–1.3 mm wide, dorsal base shallowly auriculate, overlapping the stem, apex rounded, margin plane, entire; marginal cells subquadrate, 10–15 × 8–10 µm, median and basal cells isodiametric to elongate, 15–25(–30) × 10–15(–20) µm, cell walls thickened, trigones small at leaf base increasing in size towards the margins, cuticle smooth. LOBULES distant to contiguous, subquadrate, 0.6–1 mm long, 0.4–0.7 mm wide, ca. 1/2 the lobe length, inflated at rhizoid area, insertion line inverted J-shaped, base plane on main stem, shallowly recurved on branches, rounded to slightly auriculate, covering 1/2 to fully overlapping the stem, free margin plane, straight to sinuate, apex rounded, distal margin ± straight; keel straight, spreading at angles of 50–90° with the stem. RHIZOIDS colorless to brown, numerous. ANDROECIA not seen. GYNOECIA on long branches, with 2 innovations; bracts ovate, 2.5–3.3 mm long, 0.6–0.7 mm wide, apex rounded, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded. PERIANTHS subcylindrical, 2.4–2.8 mm long, 1.3–1.5 mm wide at apex, mouth irregularly undulate. VEGETATIVE REPRODUCTION not observed.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1937, p. 30–33, Fig. 5), Solari (1978, p. 197–199, Fig. 9), Yamada (1981, p. 390–393, Figs. 15–17 as *R. plumosa*).

DISTRIBUTION AND HABITAT: Brazil, Argentina, Chile. New to Brazil, collected in Atlantic forest in Rio de Janeiro and Santa Catarina, growing on rock at 280–1010 m elevation.

TAXONOMIC NOTES: *Radula punctata* is characterized by (1) plants relatively large and regularly pinnate; (2) stem with ca. 260 cells in cross section (epidermal plus medullary cells); (3) leaf lobes shallowly imbricate, ovate; (3) lobule distant, subquadrate with slightly auriculate base, covering 1/2 to fully overlapping the stem, free margin ± straight to sinuate, apex rounded, keel ± straight, inflated at rhizoid area.

Radula punctata resembles *R. recubans* but the latter species differs in plants regularly pinnate, cuticle verruculose (smooth in *R. punctata*) and lobule with a rounded base and straight insertion line (with auriculate base and an inverted J-shaped insertion line in *R. punctata*). Váňa & Engel (2013) suggested that *R. punctata* should be called *R. plumosa* but the name *R. punctata* is older (Gradstein in press).

Radula quadrata Gottsche, Syn. Hepat. 255. 1845.

Fig. 23

TYPE: Mexico, Jalapa, unknown collector (lectotype: G-00116228!, designated here).

= *Radula mollis* Lindenb. & Gottsche, Syn. Hepat. 725. 1847, fide Yamada & Gradstein (1991).

= *Radula glauca* Steph., Sp. Hepat. 4: 175. 1910, fide Yamada (1993a).

Dioicous. PLANTS 2–2.8 mm wide, yellowish-green to brownish in herbarium, irregularly pinnate. STEMS in cross section with ca. 21–25 thick-walled epidermal cells surrounding ca. 20–32 thick-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones large. LEAVES widely spreading, imbricate, slightly convex, ovate, 1.4–1.6 mm long, 1–1.3 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane to recurved, entire to strongly crenulate when with gemmae; marginal cells subquadrate to rounded, 9–18 µm, median and basal cells isodiametric (–10)20–28 µm, cell walls evenly thickened, trigones small, cuticle smooth. LOBULES widely spreading, contiguous to imbricate, subquadrate, 0.85–1 mm long, 0.7–0.75 mm wide, ca. 1/2 the lobe length, inflated at rhizoid area and along the keel, insertion line ± straight, base plane, rounded, fully overlapping the stem, free margin plane, straight to sinuose, apex plane, rounded to obtuse, distal margin straight to sinuose; keel straight, spreading at angles of 60–80° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA not seen. GYNOECIA on short branches, with 1–2 innovations; bracts ovate to oblong, 1–1.5 mm long, 0.5–0.8 mm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHES subcylindrical, 1.6–2.5 mm long, 0.8–1.1 mm wide at apex, mouth entire, irregularly undulate. VEGETATIVE REPRODUCTION by small discoid gemmae, ca. 60–150 µm in diam., copiously produced on the margins of leaves, perianths and bracts.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1965, p. 332–334, Fig. 1, p. 334–338, Fig. 2 as *R. mollis*), Schuster (1980, p. 615–621, Figs. 626–627 as *R. mollis*), Yamada & Gradstein (1991, p. 65 and 67), Yamada (1993a, p. 133–135, Fig. 52).

DISTRIBUTION AND HABITAT: Tropical and subtropical America, ranging northwards into warm-temperate, southeastern U.S.A. In Brazil collected in Bahia, Distrito Federal, Espírito Santo, Mato Grosso do Sul, Minas Gerais, Paraná, Pernambuco, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. The species usually grows on bark, at 10–1100 m elevation.

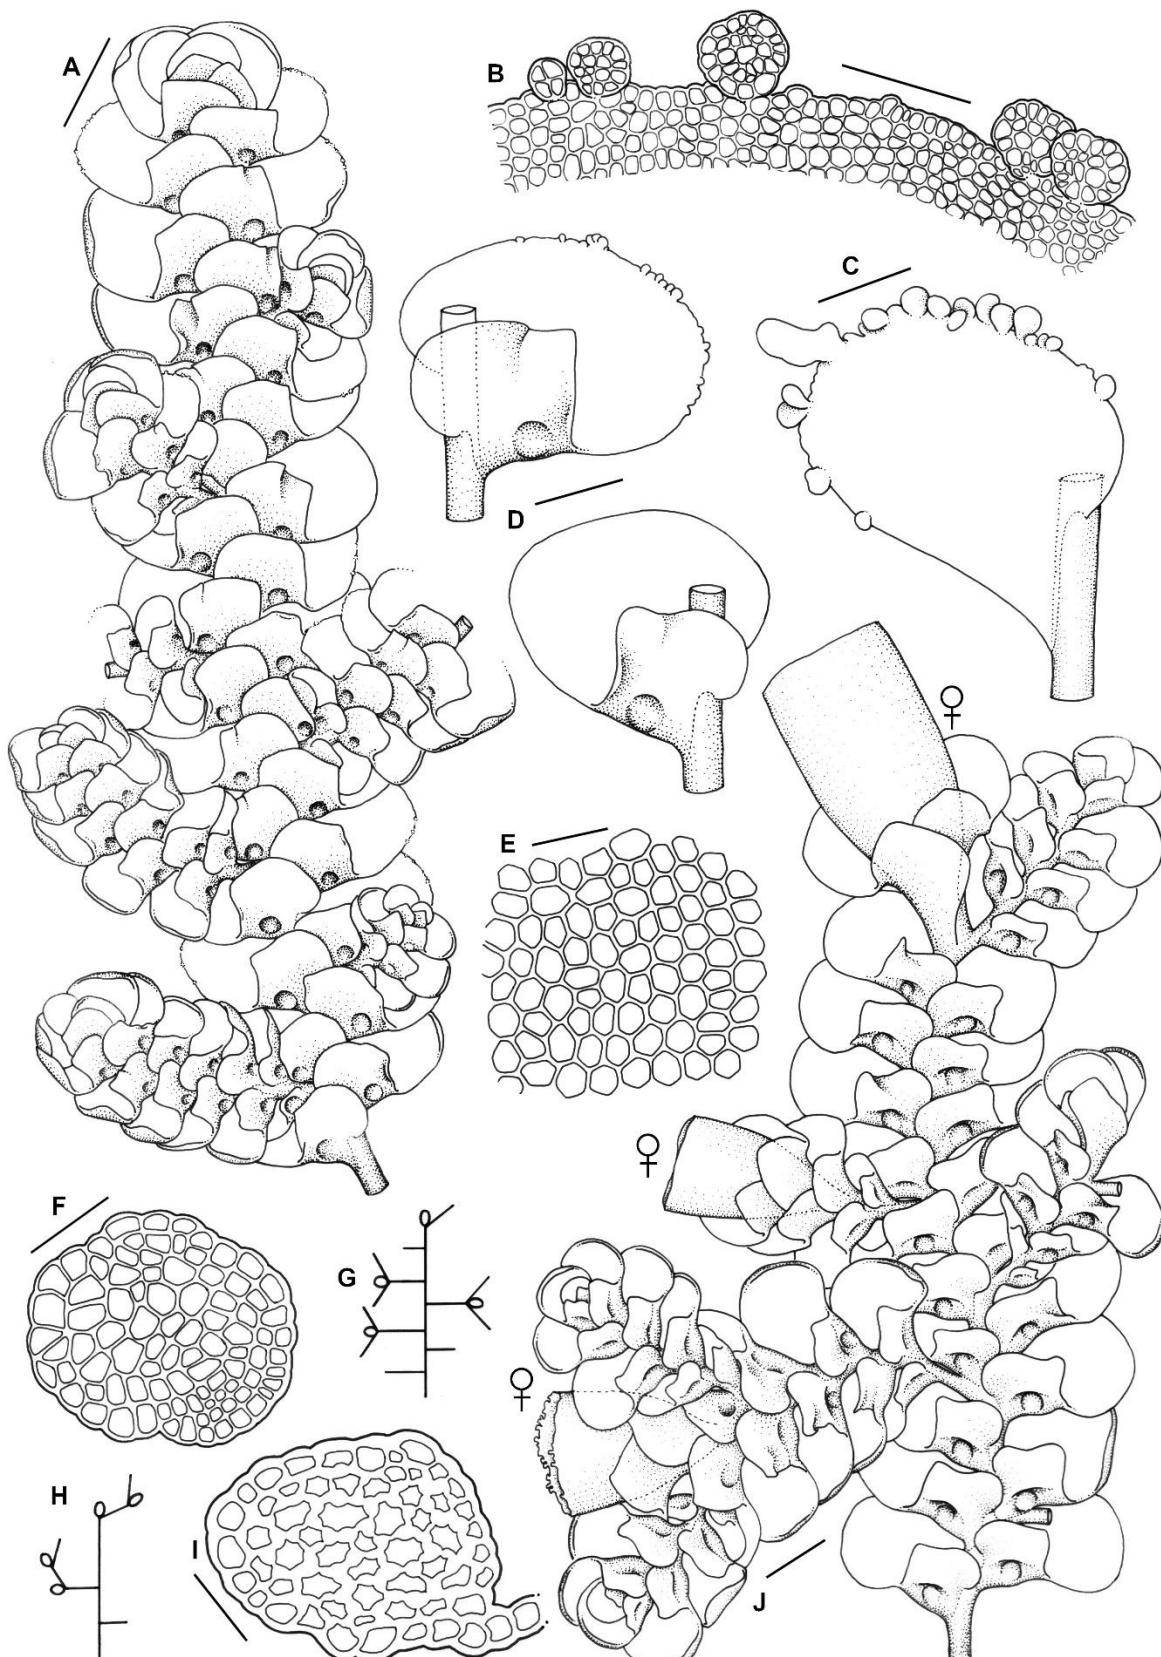

Figure 23. A-J. *Radula quadrata* – A. Habit. B. Leaf margin with gemma. C. Dorsal leaf margin with gemma. D. Leaves. E. Median leaf cells. F. Gemmae. G-H. Cladograph of fertile plants (open ellipse= gynoecia with perianth). I. Cross section of a stem. J. Habit with gynoecia (A=1000 µm; B= 100 µm; C= 250 µm; D, J= 500 µm; E, F, I= 50 µm; A, D from lectotype G00116228; B, C, E, F, I from MG130705; G, H, J from SP181497).

TAXONOMIC NOTES: *Radula quadrata* is recognized by (1) leaves convex with margins plane to recurved, entire or strongly crenulate when with gemmae; (2) lobule large, imbricate, subquadrate with rounded base, fully overlapping the stem, keel straight, inflated along the keel and at rhizoid area. Besides on leaf lobes, discoid gemmae are also produced on the perianth mouth and bract margins.

Radula quadrata resembles *R. tectiloba* by leaves ovate with margin entire to crenulate with numerous small discoid gemmae, and lobules subquadrate. However, *R. quadrata* differs by lobules $0.85-1 \times 0.7-0.75$ mm, imbricate (lobules $0.5-0.8 \times 0.3-0.5$ mm, distant to subimbricate in *R. tectiloba*) and lobule base fully overlapping the stem (usually covering 1/2 the stem in *R. tectiloba*, rarely fully overlapping).

isodiametric to elongate, 22–30 × 12–18 µm, basal cells elongate, 25–35 × 12–18 µm, cell walls thin, trigones small, cuticle verruculose. LOBULES obliquely to widely spreading, distant to contiguous, subquadrate, 0.4–0.9 (–1) mm long, 0.3–0.75 mm wide, ca. 1/2 of the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded, covering 2/3 to fully overlapping the stem, free margin plane, straight, apex plane, sometimes incurved, rounded to obtuse, distal margin sinuate; keel straight to slightly concave, spreading at angles of 40° with the stem. RHIZOIDS not seen. ANDROECIA terminal to intercalary on long branches, with 2–8 pairs of bracts, 0.75–1.1 mm wide; bracts ovate, 0.55–0.95 mm long, 0.2–0.4 mm wide, apex rounded, margin plane, rarely recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded to obtuse, free margin straight, apex obtuse. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 0.9–1.1 mm long, 0.35–0.45 mm wide, apex rounded, margin plane to recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2.5–2.9 mm long, 1–1.4 mm wide at apex, mouth entire, undulate. VEGETATIVE REPRODUCTION not observed. ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1966, p. 11–13, Fig. 3), Yamada (1980, p. 252–254, Fig. 8, 2003, Fig. 84A).

DISTRIBUTION AND HABITAT: Guatemala, Ecuador, Venezuela, Guyana, Brazil. In Brazil recorded in Amazonas, Espírito Santo, Minas Gerais, Paraná, Rio de Janeiro, Rio Grande do Sul and São Paulo. The species has been collected on tree trunks, decaying wood and rock, usually in humid places, at 300–1640 m elevation.

TAXONOMIC NOTES: *Radula recubans* is recognized by (1) plants regularly pinnate; (2) lobes widely spreading, ovate; (3) cells thin-walled, with small trigones and verruculose cuticle; (4) lobules distant to contiguous, subquadrate with rounded base, covering 2/3 to fully overlapping the stem, distal margin usually sinuose and inflated at rhizoid area. *Radula recubans* resembles *R. punctata*; for differences see under *R. punctata*.

***Radula renneri* F.R.Oliveira-da-Silva, Ilk.-Borg., Gradst. sp. nov.**

Fig. 25

DIAGNOSIS: Paroicous. Leaves ovate, margins entire to crenulate in gemmate leaves. Leaf cell walls thin, with very small trigones. Lobules subquadrate to rhombic, apex usually extended, obtuse to acute (ending in one cell), base rounded, usually covering 1/2 the stem. Gynoecia usually without innovations, rarely one. Vegetative reproduction by means of small discoid gemmae produced on leaf margins.

TYPE: Brazil, Rio de Janeiro, Teresópolis, “bairro Quebra Frascos, sobre tronco vivo, na sombra, vegetação de capoeira”, 23 March 1926, Vaughan Bandeira s.n. (holotype: RB-00709793!; isotype: MG!).

ETYMOLOGY: The new species is dedicated to Matthew A. M. Renner, renowned expert of *Radula*.

Paroicous. PLANTS 1.7–2.2 mm wide, yellowish-brown in herbarium, irregularly pinnate. STEMS in cross section with ca. 23 thick-walled epidermal cells surrounding ca. 40 thick-walled medullary cells, epidermal and medullary cells of the same size, cell walls yellowish, trigones large. LEAVES obliquely to widely spreading, subimbricate, convex, ovate, 1–1.8 mm long, 0.8–1.7 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin plane to slightly recurved, entire to crenulate in gemmate leaves; marginal cells subquadrate to isodiametric, 10–15 × 8–10 µm, median cells isodiametric, 20–25 µm in diam., basal cells elongate, 25–35(–40) × 20–30 µm, cell walls thin, trigones very small, cuticle finely papillose. LOBULES distant, subquadrate to rhombic, 0.5–0.9 mm long, 0.45–0.8 mm wide, 2/5–1/2 the lobe length, insertion line straight, base plane, rounded, covering 1/2 the stem, rarely more, free margin plane, straight, apex plane, usually elongate, obtuse to acute (ending in one cell), distal margin straight; keel straight, spreading at angles of 45–65° with the stem, lobules inflated at rhizoid area. RHIZOIDS colorless, scanty. ANDROECIA on short branches, terminal or preceding the gynoecia, with 1–3 pairs of bracts, 1–1.3 mm wide; bracts ovate, 0.8–1 mm long, 0.5–0.65 mm wide, apex rounded, margin plane to recurved, entire, lobule ovate, 3/4 of the lobe-length, base rounded to obtuse, free margin straight, apex rounded to obtuse. GYNOECIA on short branches, with 0(–1) innovation; bracts ovate, 0.9–1.1 mm long, 0.5–0.8 mm wide, apex rounded, margin plane, entire, lobule oblong, 1/3–1/2 of lobe length, apex rounded to obtuse. PERIANTHS trumpet-shaped to subcylindrical, 1.4–2.3 mm long, 1–1.5 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by small discoid gemmae, ca. 65 µm in diam., produced on leaf margins.

DISTRIBUTION AND HABITAT: The new species is in Brazil only known from Rio de Janeiro State. The species was growing on a living tree trunk in a secondary, Atlantic rainforest in the surroundings of Teresópolis.

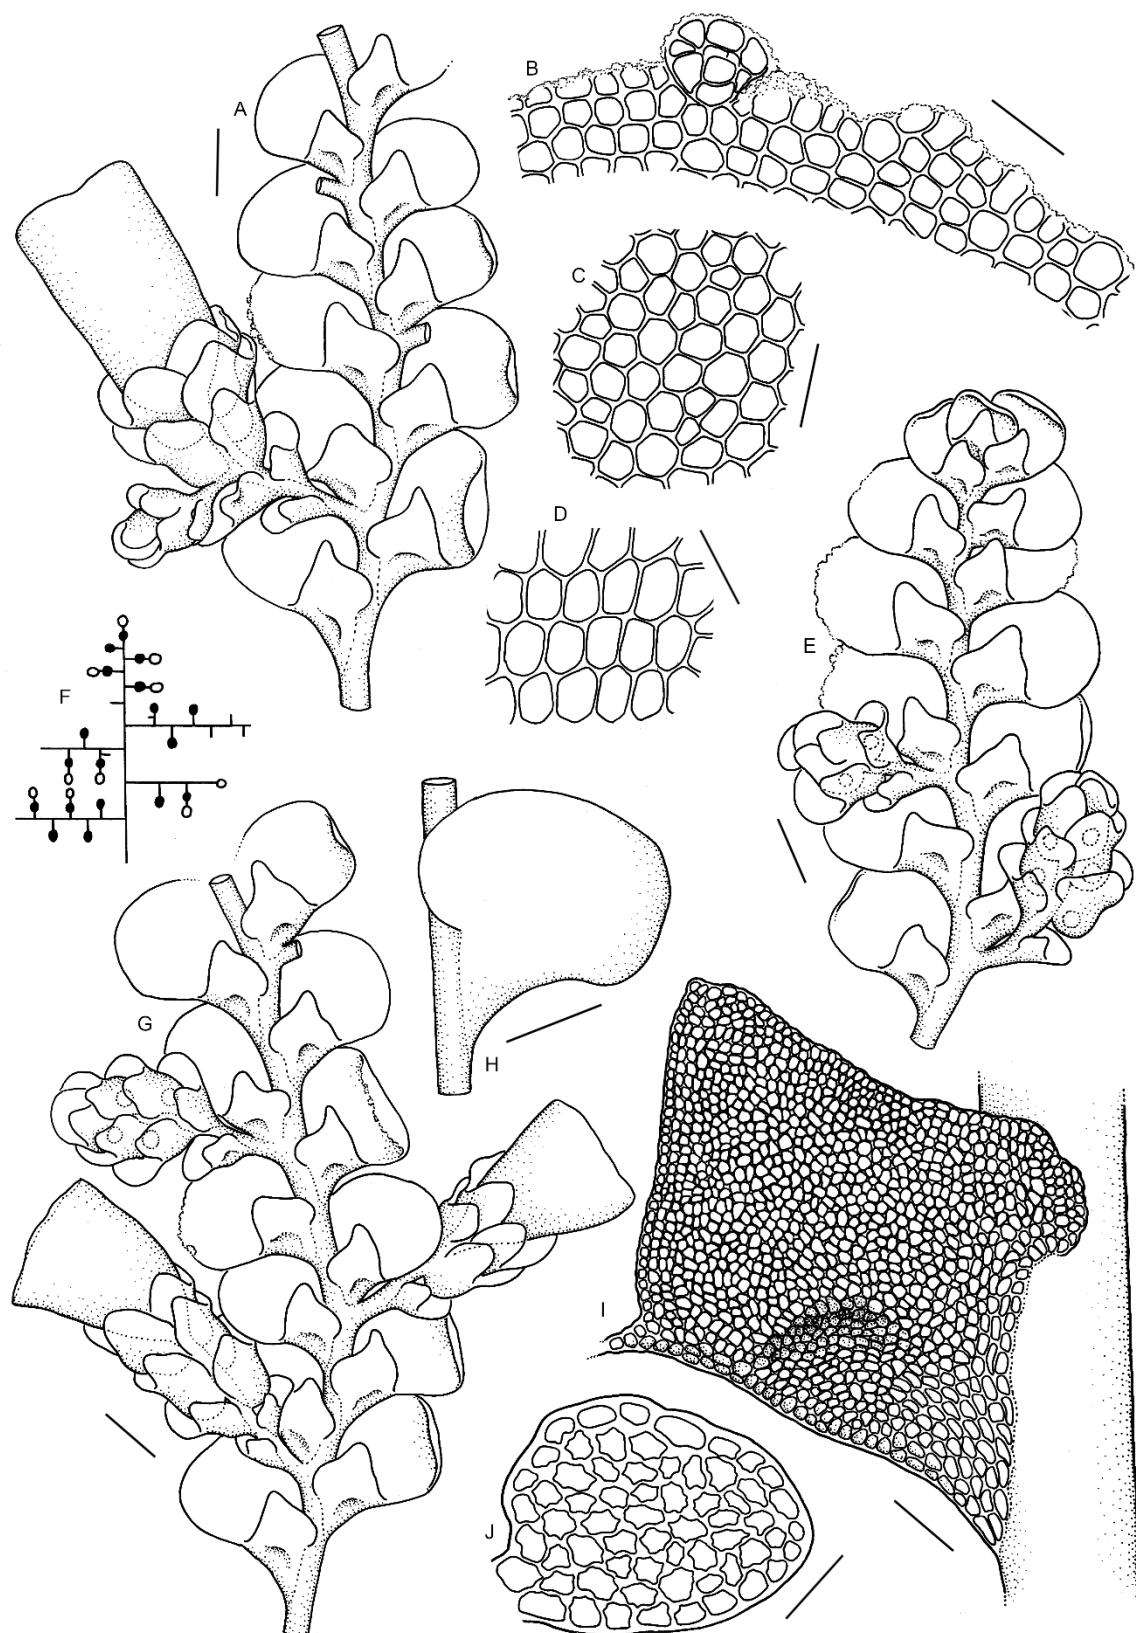

Figure 25. A-J. *Radula renneri* - A, E, G. Habit. B. Leaf margin with gemma. C. Median leaf cells. D. Basal leaf cells. F. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). H. Leaf, dorsal view. I. Lobule. J. Cross section of a stem. (A, E, G, H= 500 µm; B, C, D, J= 50 µm; I= 100 µm; A-J from the holotype).

TAXONOMIC NOTES: *Radula renneri* is recognized by its paroicous condition, leaf margins entire to crenulate in gemmate leaves, leaf cell walls thin, with very small trigones, lobules subquadrate to rhombic, with a usually extended, obtuse to acute (ending in one cell) apex and a rounded base, the base covering $\pm 1/2$ the stem width (rarely more), gynoecia with 0(–1) innovation, and vegetative reproduction by means of small discoid gemmae produced on leaf margins.

The new species was initially thought to be *Radula complanata*, which has been reported several times from Brazil as well as from other tropical and subtropical regions, but all these records are erroneous or highly doubtful (Yamada 1979, 2003). *Radula renneri* and *R. complanata* share paroicous sexuality and the presence of small discoid gemmae on leaf margins. However, *R. complanata* differs in the smooth cuticle and narrowly rounded to obtuse lobule apex (very rarely subacute). Additionally, *R. complanata* has slightly smaller lobules. The new species is also similar to *R. tectiloba* in lobule shape and presence of discoid gemmae on leaf margins, but the latter species differs in dioicous sexuality and slightly smaller lobules with the apex not extended and usually rounded (rarely obtuse).

Before this study, *Radula mexicana* was the only monoicous species registered from Brazil (Yamada 2003, BFG 2018). This latter species, however, is autoicous, produces innovations (usually two per gynoecium) and lacks gemmae.

Radula schaefer-verwimpii K.Yamada, J. Jap. Bot. 65: 3. 1990.

Fig. 26

TYPE: Brazil, Minas Gerais, National Park Serra do Caparaó, “auf schattigem Felsblock,” 1360 m, 28 July 1987, Schäfer-Verwimp 8989 (isotypes: G-00265052!, SP-383443!, NY-01021153!, NY-01021154!, GOET-012152!, GOET-012153!).

Dioicous. PLANTS 0.6–1.2 mm wide, green to olive-green in herbarium, irregularly pinnate. STEMS in cross section with ca. 16 thick-walled epidermal cells surrounding ca. 12 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls colorless, trigones lacking. LEAVES widely spreading, distant to contiguous, convex, ovate to falcate-ovate, 0.6–0.9 mm long, 0.4–0.7 mm wide, dorsal base rounded, not overlapping the stem, apex obtuse, margin plane, entire; marginal cells isodiametric, 8–15 μm in diam., median cells isodiametric to elongate, 15–20 \times 10–15 μm , basal cells isodiametric to elongate, 20–25 \times 10–15 μm wide, cell walls thin, trigones lacking, cuticle smooth. LOBULES distant, subquadrate to rhombic, 0.3–0.5 mm long, 0.15–0.25 mm wide, ca. 1/2 the lobe length, inflated at rhizoid area, insertion line arched, base plane, rounded, covering 1/5–1/3 the stem, free margin plane, straight,

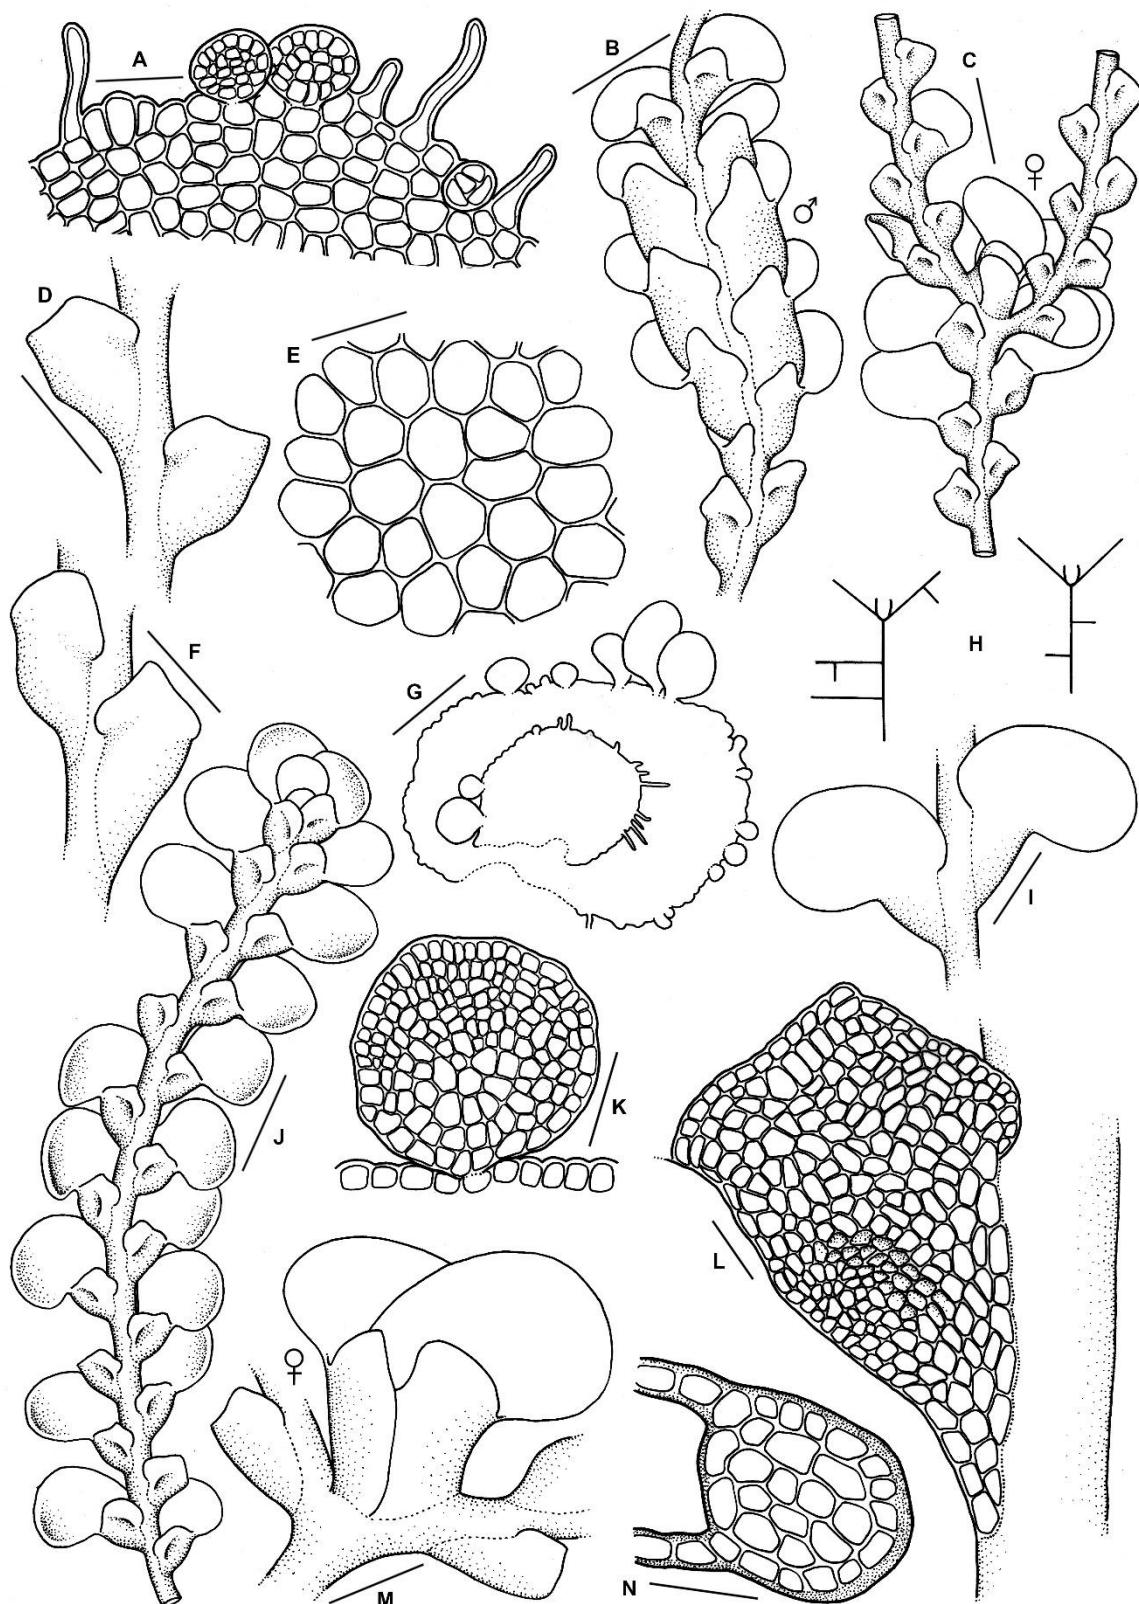

Figure 26. A-N. *Radula schaefer-verwimpii* - A. Marginal leaf cells with regenerants and rhizoids. B. Habit with androecia. C. Habit with gynoecia. D, F, L. Lobules. E. Median leaf cells. G. apex plane, rounded to obtuse, distal margin straight; keel strongly convex, spreading at angles of 30–40° with the stem. RHIZOIDS colorless, scanty. ANDROECIA intercalary on short branches, with 2–4 pairs of bracts, 0.7–1.1 mm wide; bracts ovate, 0.6–0.9 mm long, 0.25–0.4 mm wide, apex rounded, margin plane to recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex obtuse. GYNOECIA on short branches, with two innovations; bracts oblong-ovate, 0.7–0.85(–0.9) mm long, 0.3–0.4 mm wide, apex rounded, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS not seen. VEGETATIVE REPRODUCTION by caducous leaf lobes, producing completely denuded branches, and by discoid gemmae, 50–130 µm in diam., produced on leaf margins.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Yamada (1990, p. 3–6, Fig. 2).

DISTRIBUTION AND HABITAT: Guyana, Venezuela, Colombia, Ecuador, Bolivia and Brazil. In Brazil recorded in Espírito Santo, Minas Gerais, Paraná, Rio de Janeiro and São Paulo. The species usually grows on rock and soil, rarely on tree trunks, in Atlantic forest, at 1000–2400 m elevation.

TAXONOMIC NOTES: *Radula schaefer-verwimpii* differs from other Brazilian species of *Radula* in the following combination of characters: (1) plants with strongly caducous leaf lobes; (2) leaves ovate to falcate-ovate with rounded apex; (3) lobules small, distant, subquadrate to rhombic, base covering only 1/5–1/3 the stem, keel convex. This is the most fragile species among Brazilian *Radulas*; the branches are usually devoid of leaf lobes.

This species resembles *R. pocsii* by caducous leaf lobes, producing almost completely denuded branches, leaves ovate to falcate-ovate, and lobule shape with keel straight, spreading at angles of 30–40° with the stem. However, *R. schaefer-verwimpii* differs by the stem anatomy, plants usually 0.6–1.2 mm wide (1.5–2 mm in *R. pocsii*), and leaf cells without trigones (trigones small at leaf base and increasing in size towards the margins in *R. pocsii*). *Radula schaefer-verwimpii* also resembles *R. brasiliaca*; differences are given under *R. brasiliaca* and in the key.

TYPE: Brazil, Minas Gerais, Caldas, 1854, Lindberg s.n. (lectotype: G-00282150!, designated by Yamada 1987; isolectotype: G-00282151!).

= *Radula montana* Steph., Sp. Hepat. 4: 176. 1910. TYPE: Brazil, Paraná, Serra do Mar, 29 January 1907, Dusén 3478 (lectotype: G-00043901!, designated by Yamada 1987).

= *Radula obtusifolia* Steph., Sp. Hepat. 4: 178. 1910, fide Castle (1965).

Dioicous. PLANTS 1.3–2.2 mm wide, yellow to yellowish-brown in herbarium, irregularly pinnate. STEMS in cross section with ca. 41 thick-walled epidermal cells surrounding ca. 75 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones lacking. LEAVES obliquely to widely spreading, imbricate, convex, ovate to falcate-ovate, 0.8–1 mm long, 0.6–0.9 mm wide, dorsal base rounded to shallowly auriculate, overlapping the stem, apex rounded, margin plane to recurved, entire; marginal cells subquadrate to isodiametric, 8–15 µm in diam., median and basal cells isodiametric to elongate, 20–25 × 15–20 µm, cell walls thin, trigones lacking, cuticle smooth. LOBULES contiguous to imbricate, subquadrate, 0.5–0.8 mm long, 0.5–0.8 mm wide, ca. 1/2 the lobe length, inflated at rhizoid area, insertion line circinate, base plane, short-auriculate, covering 3/4 to fully overlapping the stem, free margin plane to incurved, broadly rounded, apex plane, rounded to obtuse, distal margin sinuate; keel ± straight to convex, spreading at angles of 60° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal on short branches, with 2–6 pairs of bracts, 1–1.5 mm wide; bracts distant to imbricate, ovate, 0.8–1 mm long, 0.25–0.4 mm wide, apex rounded, margin plane to recurved, entire, lobule imbricate, oblong, ca. 3/4 of lobe length, base rounded, free margin ± straight, apex obtuse. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 1–1.4 mm long, 0.5–0.6 mm wide, apex rounded, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex obtuse to subacute. PERIANTHS subcylindrical, 3.3–4 mm long, 1.2–1.7 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by caducous leaves (rare) and regenerants.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1965, p. 345–348, Fig. 5 as *R. montana*, p. 348–350, Fig. 6), Yamada (1987, p. 294–295, Fig. 35 as *R. montana*, p. 297–298, Fig. 37, 2003, Fig. 83D), Reiner-Drehwald (1994, p. 16–17, Fig. 1A as *R. montana*), Lemos-Michel (2001, p. 162–165, Fig. 46 as *R. montana*).

DISTRIBUTION AND HABITAT: Costa Rica to Bolivia, Brazil and Argentina. In Brazil registered from Bahia, Espírito Santo, Minas Gerais, Paraná, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. This species is usually found growing on bark, rarely on rock or decaying wood, at 600–1900 m elevation.

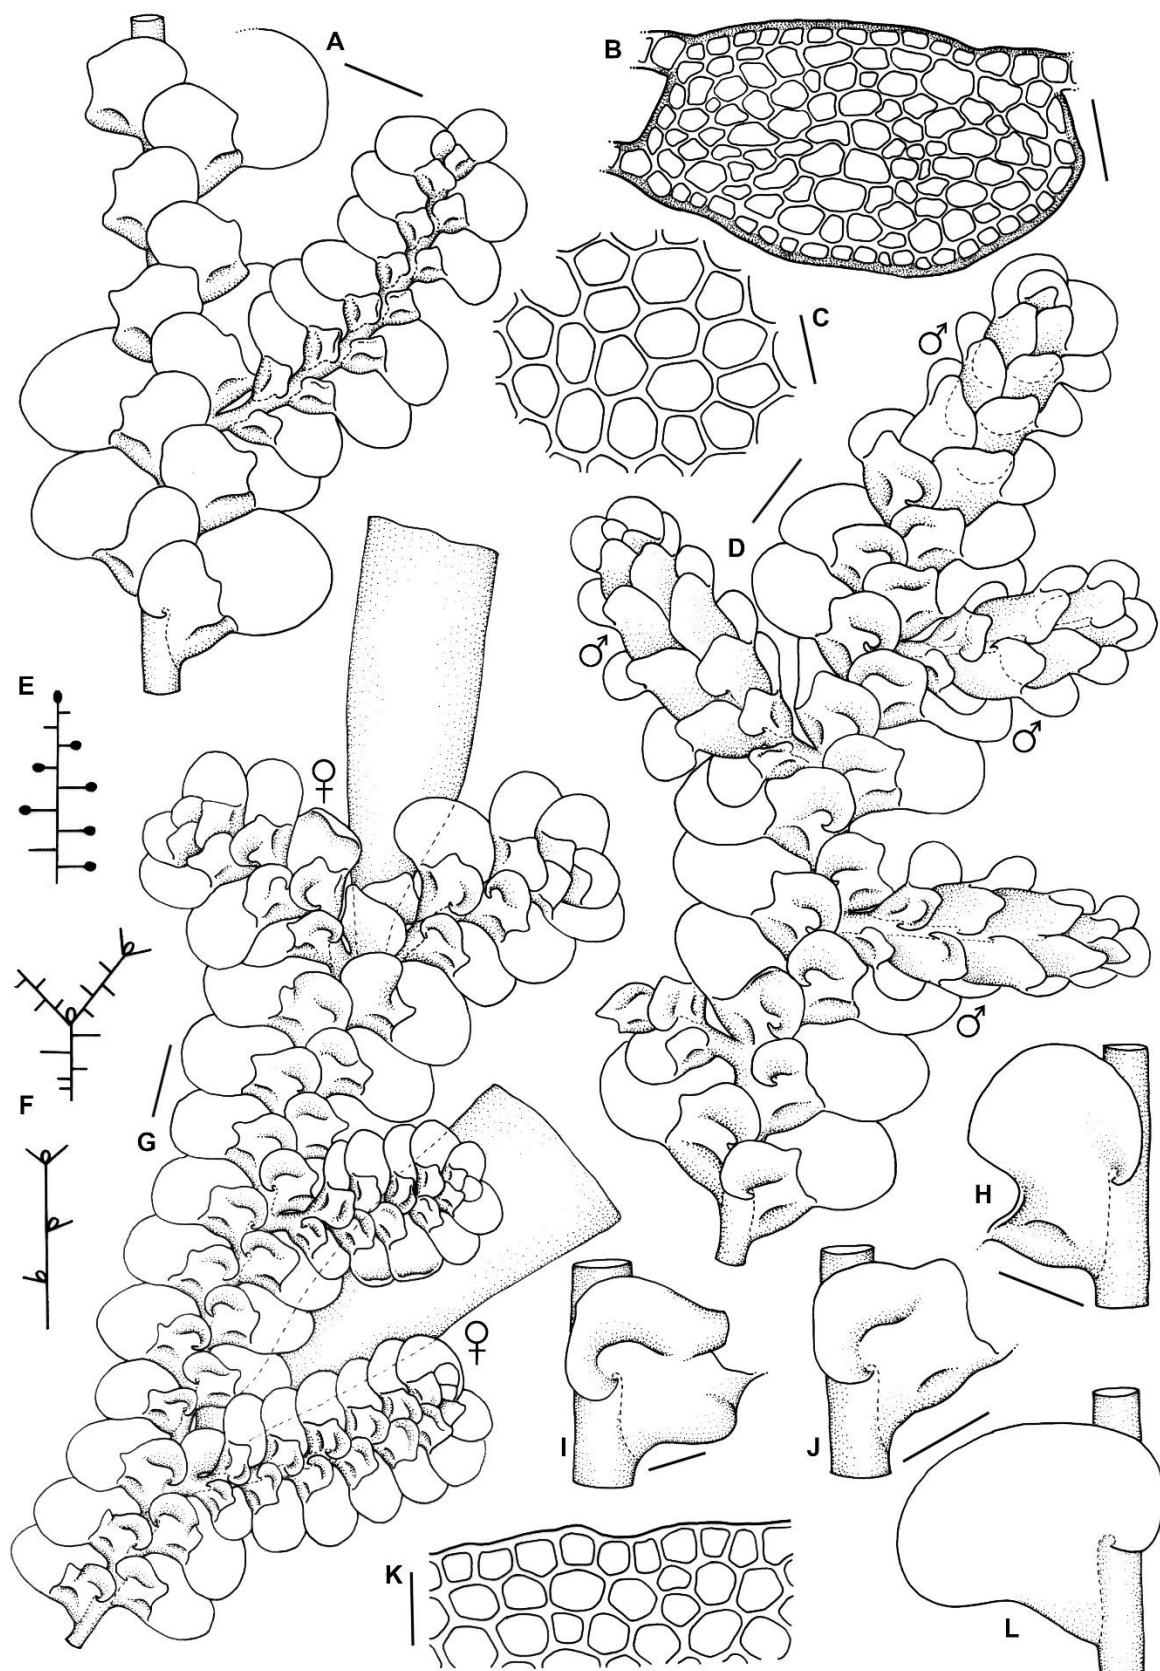

Figure 27. A-L. *Radula sinuata* - A. Habit. B. Cross section of a stem. C. Median leaf cells. D. Habit with androecia. E-F. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). G. Habit with gynoecia. H-J. Lobule. K. Marginal leaf cells. L. Leaf, dorsal view. (A, D, G, J, L= 500 μm ; B= 50 μm ; C, K= 25 μm ; H= 250 μm ; I= 162 μm ; A from SP379616; B-C, I-L from lectotype G00282150; D-E from SP455594; F-G from SP407257; H from SP280499).

TAXONOMIC NOTES: *Radula sinuata* is easily recognized by lobules contiguous to imbricate, subquadrate, insertion line circinate, base short-auriculate, frequently fully overlapping the stem, free margin broadly rounded, apex broadly rounded to obtuse, distal margin sinuate, keel ± straight to convex.

Radula sinuata resembles *R. voluta* in stem anatomy, leaf shape and the auriculate lobule base. However, *R. sinuata* differs by lobule base short-auriculate (strongly auriculate or circinately coiled in *R. voluta*) and cells without trigones (trigones small at leaf base and increasing in size towards the margins, becoming bulging, in *R. voluta*).

1/3 of the lobe length, strongly inflated at rhizoid area, insertion line straight, base plane, not covering the stem, free margin plane, straight, apex plane, rounded, distal margin straight to sinuose; keel convex, spreading at angles of ca. 50° with the stem. RHIZOIDS colorless to brown, numerous on a pronounced mammiliform swelling. ANDROECIA terminal on long branches, with

2–10 pairs of bracts, 300–400 µm wide; bracts ovate, 0.2–0.3 mm long, 0.1–0.2 mm wide, apex rounded, margin recurved, entire, lobule ovate, ca. 5/6 of lobe length, base slightly rounded to straight, free margin straight, apex rounded. GYNOECIA on long branches, with 1–2 innovations; bracts oblong, 0.5–0.6 mm long, 0.2–0.3 mm wide, apex rounded, margin plane to recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded. PERIANTHS trumpet-shaped to subcylindrical, 1.5–2 mm long, 0.2–0.3 mm wide at apex, mouth irregularly undulate to entire. VEGETATIVE REPRODUCTION by discoid gemmae, 44–200 µm in diam., produced on leaf margins.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1939, p. 36–39, Fig. 6), Yamada (1993a, p. 135–136, Fig. 53 based on isotype of *R. tenella*), Promma & Chantanaorrapint (2015, p. 229–230, Figs. 64–83).

DISTRIBUTION AND HABITAT: Tropical America, tropical Africa, Asia. In Brazil it occurs in Amazonas, Pará, Paraná, Rio de Janeiro and São Paulo. The species usually grows on living leaves, at 300–1100 m elevation.

TAXONOMIC NOTES: *Radula stenocalyx* is characterized by (1) plants epiphyllous; (2) leaves widely spreading with numerous small, discoid gemmae on the margins; (3) leaf cells without trigones; (4) lobules distant, subquadrate, base not covering the stem, apex usually rounded, keel convex, and with a pronounced mammiliform swelling at rhizoid area.

Radula stenocalyx resembles *R. flaccida* and *R. yanoella*; for differences see under *R. flaccida*.

Radula subinflata Lindenb. & Gottsche, Syn. Hepat. 724. 1847.

Fig. 29

TYPE: Mexico, Sempaltepec, Liebmann s.n. (isotype: G-00124238!).

Dioicous. PLANTS 1.3–2.4 mm wide, green to yellowish-green in herbarium, irregularly pinnate. STEMS in cross section with ca. 25 thick-walled epidermal cells surrounding ca. 26 thick-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown,

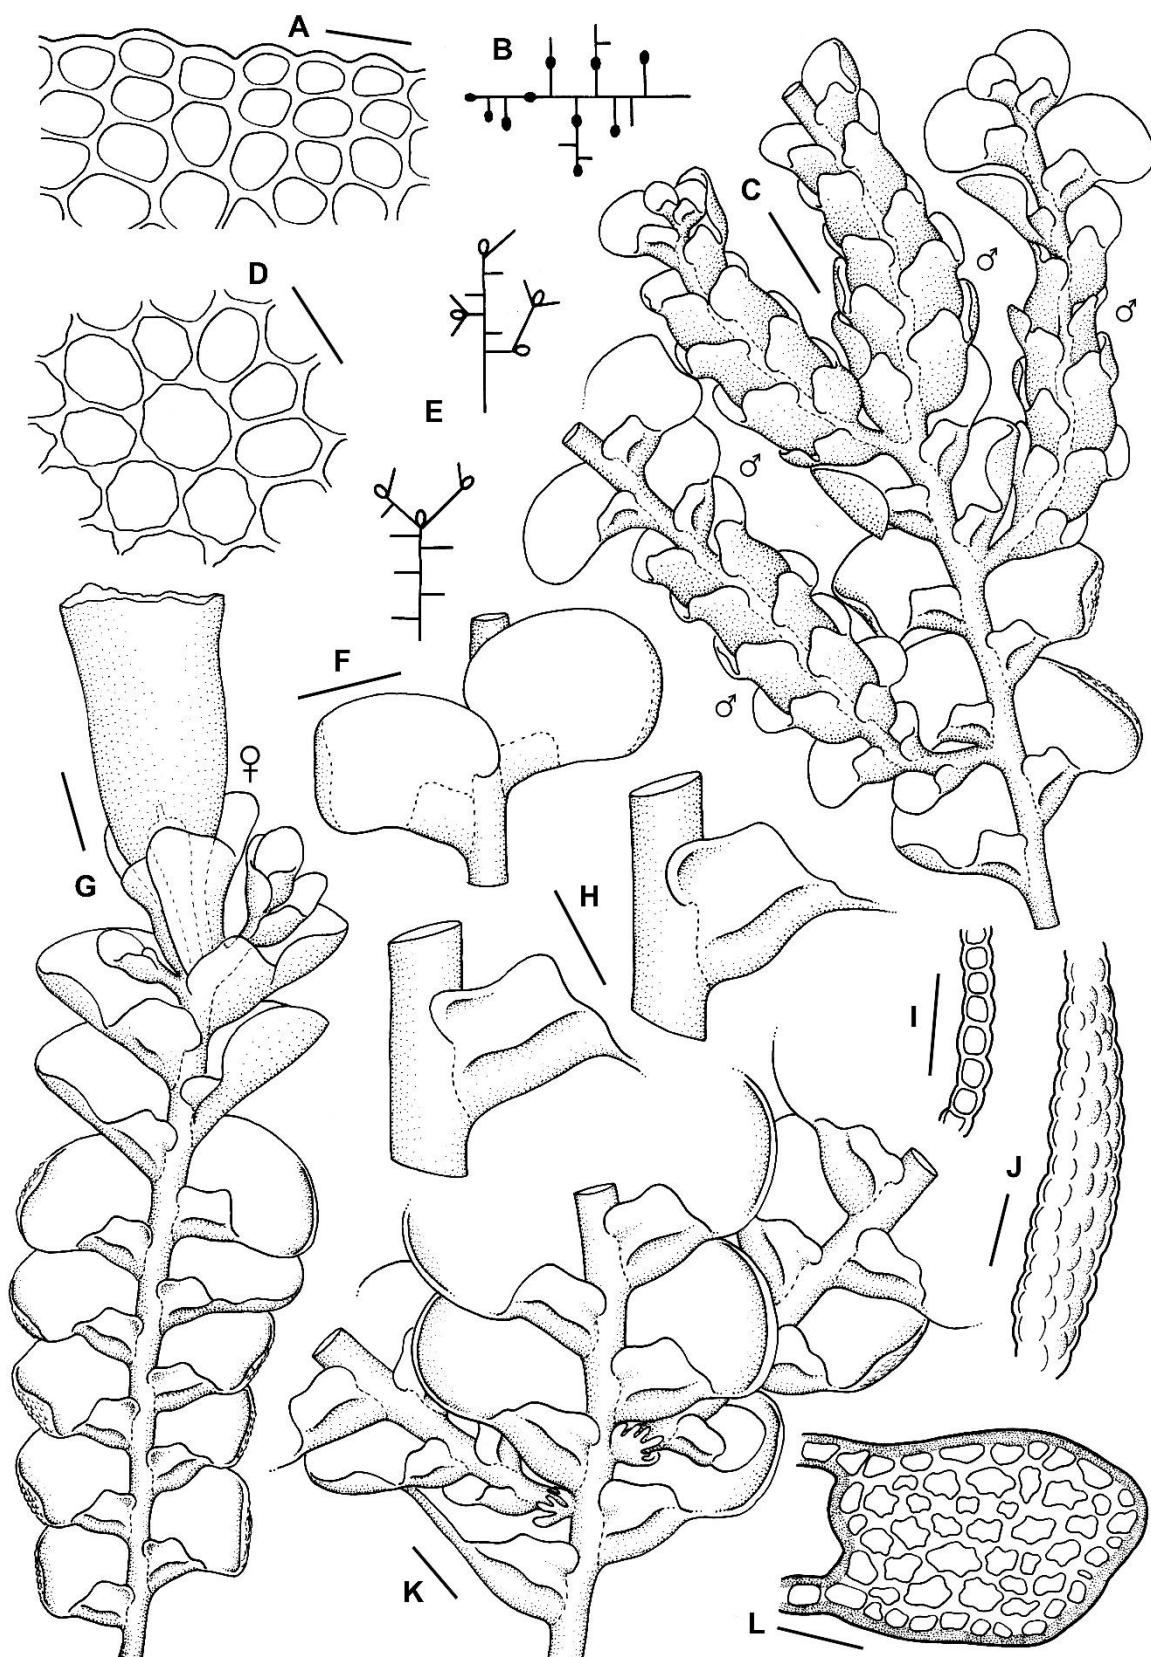

Figure 29. A-L. *Radula subinflata* – A. Marginal leaf cells. B, E. Cladograph of fertile plants (open ellipse= gynoecia with perianth; solid ellipse= androecia). C. Habit with androecia. D. Median leaf cells. F. Leaves, dorsal view. G. Habit with gynoecia. H. Lobules. I. Cross section of a leaf. J. Dorsal leaf with mammillose cells. K. Habit. L. Cross section of a stem (A, D= 25 μ m; C, F, G, K= 500 μ m; H= 250 μ m; I, J, L= 50 μ m; A, D-L from MG130701; B-C from SP407308).

medullary cell walls yellowish, trigones large. LEAVES widely spreading, contiguous to imbricate, strongly convex, ovate to falcate-ovate, 0.7–1 mm long, 0.45–0.8 mm wide, dorsal base rounded, overlapping the stem, apex rounded, margin recurved, slightly crenulate; marginal cells isodiametric, 8–10 μm in diam., median and basal cells isodiametric to elongate, 10–15 \times 15–25 μm , cell walls thin, mammillose on the dorsal lobe surface, trigones small, cuticle smooth. LOBULES distant, (sub)quadrate, 0.4–0.5 mm long, 0.3–0.4 μm wide, 1/3–1/2 the lobe length, strongly inflated along the keel, insertion line \pm straight, base plane to slightly recurved, rounded, covering up to 1/4 the stem, free margin plane to sinuate, straight, apex rounded, distal margin \pm straight; keel straight to slightly convex, spreading at angles of 40–60° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal to intercalary on long branches, with 3–6 pairs of bracts, 0.8–1 mm wide; bracts ovate, 0.6–0.7 mm long, 0.3–0.35 mm wide, margin recurved, entire, apex rounded, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin straight, apex obtuse, keel convex, inflated. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 1–1.2 mm long, 0.6–0.7 mm wide, margin recurved, entire, apex rounded, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2–3.5 mm long, 0.9–1.1 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by stem fragmentation and caducous *Lejeunea*-type branches.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1963, p. 13–15, Fig. 5), Yamada & Gradstein (1991, p. 67–68).

DISTRIBUTION AND HABITAT: Tropical and subtropical America. In Brazil occurring in Bahia, Minas Gerais, Paraná, Rio de Janeiro, Rio Grande do Sul, Santa Catarina and São Paulo. The species grows in Atlantic forest, usually on tree trunks and decaying wood, rarely on rock, at 1000–2500 m elevation.

TAXONOMIC NOTES: *Radula subinflata* is readily recognized by (1) leaves widely spreading, ovate to falcate-ovate, convex, margins crenulate and recurved; (2) leaf cells dorsally mammillose; (3) lobules distant, (sub)quadrate, with base plane to slightly recurved, covering up to 1/4 the stem, keel straight to slightly convex, lobule strongly inflated along the keel.

Radula subinflata is similar to *R. javanica* in the shape of leaf lobes (ovate to falcate-ovate) and lobules (sub)quadrate. It differs from *R. javanica*, however, in the lobule inflated along the keel (lobule inflated only in rhizoid area in *R. javanica*). Moreover, *R. subinflata* is the only Brazilian species with leaf cells conspicuously mammillose dorsally and leaf margins crenulate without occurrence of gemmae. In other *Radula* species in Brazil, crenulate leaf margins are only seen in connection with presence of gemmae.

(A, D, H, I= 500 µm; B-C, E= 250 µm; F, L= 50 µm; G= 25 µm; A, B-C, E, F-H, K from isotype G00281377; D, J from ICN010297; I, K from ICN11469).

long branches, with 4–8 pairs of bracts, 0.6–0.8 mm wide; bracts distant to subimbricate, ovate, 0.4–0.5 µm long, 0.25–0.3 mm wide, apex rounded, margin recurved, entire to crenulate, lobule ovate, 3/4 of lobe length, base rounded, free margin straight, apex obtuse. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 0.8–0.9 mm long, 0.5–0.6 mm wide, apex rounded, margin recurved, entire to crenulate, lobule oblong-ovate, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 1.7–2.2 mm long, 0.9–1.1 mm wide at apex, mouth entire to irregularly undulate-crenulate. VEGETATIVE REPRODUCTION by numerous small discoid gemmae, 30–60 µm in diam., produced on the margins of leaves, perianths and bracts.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1964, p. 187–190, Fig. 1), Yamada (1981, p. 395–398, Figs. 20–22, 2003, Fig. 82F), Reiner-Drehwald (1994, p. 15–16, Fig. 2C–D as *R. aurantii*), Lemos-Michel (2001, p. 165–167, Fig. 47), Gradstein & Ilkiu-Borges (2009, p. 40–41, Fig. 22H as *R. aurantii*).

DISTRIBUTION AND HABITAT: Tropical and subtropical America. In Brazil registered from Bahia, Espírito Santo, Goiás, Mato Grosso do Sul, Paraná, Rio Grande do Sul, Santa Catarina and São Paulo. The species colonizes bark of living trees, rotten wood and rock, in *Araucaria* and Atlantic forests, at 50–1600 m elevation.

TAXONOMIC NOTES: *Radula tectiloba* is characterized by (1) leaf apex recurved, margin entire, or crenulate when producing gemmae; (2) lobules distant to subimbricate, subquadrate to subrectangular, with apex rounded to acute, rarely obtuse, base covering ca. 1/2 the stem, rarely fully overlapping the stem; (3) plants with numerous small discoid gemmae, especially on leaf margins. This species is highly variable morphologically, especially its lobules. In Brazil it may be confused with *R. quadrata* (see comments under *R. quadrata*). The species is also similar to *R. renneri* (see under the latter species).

Yamada (1981) considered *R. aurantii* conspecific with *R. tectiloba* whereas Reiner-Drehwald (1994) recognized the two as distinct species. The latter author pointed out that *R. aurantii* has widely spreading leaves, keel usually concave (“incurved”), and lobule free margin convex in the lower half, while *R. tectiloba* has leaves obliquely spreading, keel usually convex and free margin plane throughout. In our study, however, we found that leaves in *R. tectiloba* vary from obliquely to widely spreading, the keel varies from concave to straight to convex and the lobule free margin from plane to recurved. Therefore, we treat *R. aurantii* as a synonym of *R. tectiloba* following Yamada (1981).

rhizoid area, insertion line circinate, base plane, fully overlapping and extending beyond the stem, strongly auriculate, the auricle circinately coiled, reaching downwards maximally to the keel (not beyond the keel), free margin plane, straight to \pm rounded, apex plane, rounded to obtuse, distal margin straight to sinuate; keel straight, spreading at angles of 55–75° with the stem. RHIZOIDS colorless, scanty. ANDROECIA terminal to intercalary on short branches, with 3–8 pairs of bracts, 0.7–1.2 mm wide; bracts ovate, 0.7–1 mm long, 0.25–0.4 mm wide, apex rounded, margin plane to recurved, entire, lobule ovate, ca. 3/4 of lobe length, base rounded, free margin \pm straight, apex obtuse. GYNOECIA on long branches, with two innovations; bracts ovate, 1–1.5 mm long, 0.4–0.7 mm wide, apex rounded, margin recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded. PERIANTHS subcylindrical, 3.5–4.2 mm long, 1–1.5 mm wide at apex, mouth entire to irregularly crenulate. VEGETATIVE REPRODUCTION by fragmentation of leaf lobes.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1965, p. 339–343, Fig. 3, as *Radula ramulina*, p. 352–355, Fig. 8), Jans (1979, p. 427–428 as *R. ramulina*, p. 428–429 as *R. ramulina* var. *microphylla*), Schuster (1980, p. 622–627, Fig. 628), Yamada & Gradstein (1991, p. 68), Reiner-Drehwald (1994, p. 18–20, Fig. 3A–C), Lemos-Michel (2001, p. 168–170, Fig. 48).

DISTRIBUTION AND HABITAT: Pantropical and northwestern Europe. In Brazil recorded from Espírito Santo, Minas Gerais, Paraná, Rio de Janeiro, Rio Grande do Sul and Santa Catarina. This species usually grows on bark and rock in Atlantic forest, at 900–1550 m elevation.

TAXONOMIC NOTES: *Radula voluta* is characterized by (1) plants regularly (bi)pinnate; (2) stem with ca. 200 cells in cross section (epidermal plus medullary cells); (3) leaves distant to contiguous, orbicular to ovate, sometimes falcate-ovate; (4) lobule contiguous to imbricate, subquadrate to suborbicular, free margin \pm straight to rounded, arching towards the large auriculate base, which is circinately coiled across and beyond the stem and reaches downwards maximally to the keel (not beyond the keel), apex rounded to obtuse, keel straight, inflated.

Radula voluta resembles *R. sinuata* and *R. gottscheana* in the auriculate lobule base, but strikingly differs in other aspects (see comments under the latter two species). Castle (1965) described vegetative reproduction in *R. voluta* by means of regeneration from the dorsal leaf lobe, which he considered occasionally caducous. Schuster (1980), however, described and illustrated *R. voluta* with small discoid gemmae on leaf margins (p. 625, Fig. 628 2–4). Reiner-Drehwald (1994), instead, observed that the gemmae reported by Schuster were early stages of regenerant development and that vegetative reproduction in *R. voluta* is usually by means of leaf lobe fragmentation. Our study of the species in Brazil and in the Andes confirms the latter observation.

Dioicous. PLANTS 2.5–3.5(–4) mm wide, yellowish-brown in herbarium, regularly pinnate to dichotomous. STEMS in cross section with ca. 39 thick-walled epidermal cells surrounding ca. 84 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal cell walls brown, medullary cell walls yellowish, trigones lacking. LEAVES widely spreading to squarrose, distant to contiguous, slightly convex, ovate to falcate-ovate, 1.2–1.5 mm long, 1–1.3 mm wide, dorsal base rounded, overlapping the stem, apex rounded to obtuse, margin plane, entire; marginal cells subquadrate to isodiametric, 15–20 × 10–12 µm, median and basal cells isodiametric to elongate, 20–30 × 15–20 µm, cell walls thin, trigones small to lacking, cuticle smooth. LOBULES distant to contiguous, (sub)quadrate, 0.5–0.8 mm long, 0.3–0.5 mm wide, ca. 1/3 the lobe length, inflated at rhizoid area, insertion line straight, base plane, rounded, covering 3/4 to usually fully overlapping the stem, free margin plane, straight to incurved, apex plane to incurved, rounded to obtuse, distal margin usually incurved; keel concave, rarely straight, spreading at angles of 25–40° with the stem. RHIZOIDS colorless to brown, scanty. ANDROECIA not seen. GYNOECIA on long branches, with 1–2 innovations; bracts ovate, 1.3–1.4 mm long, 0.7–0.8 mm wide, apex rounded, margin plane to recurved, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, 2.3–3.5 mm long, 1–1.1 mm wide at apex, mouth entire to irregularly undulate. VEGETATIVE REPRODUCTION by caducous leaf lobes.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Castle (1966, p. 35–38, Fig. 14), Yamada (1982, p. 453–454, Fig. 25 as *R. frondescens*).

DISTRIBUTION AND HABITAT: Ecuador, Colombia, Peru, Bolivia, Brazil, Chile. The species is a new record for Brazil (Rio de Janeiro), occurring on rocks near a water course in Atlantic forest, at 900 m elevation.

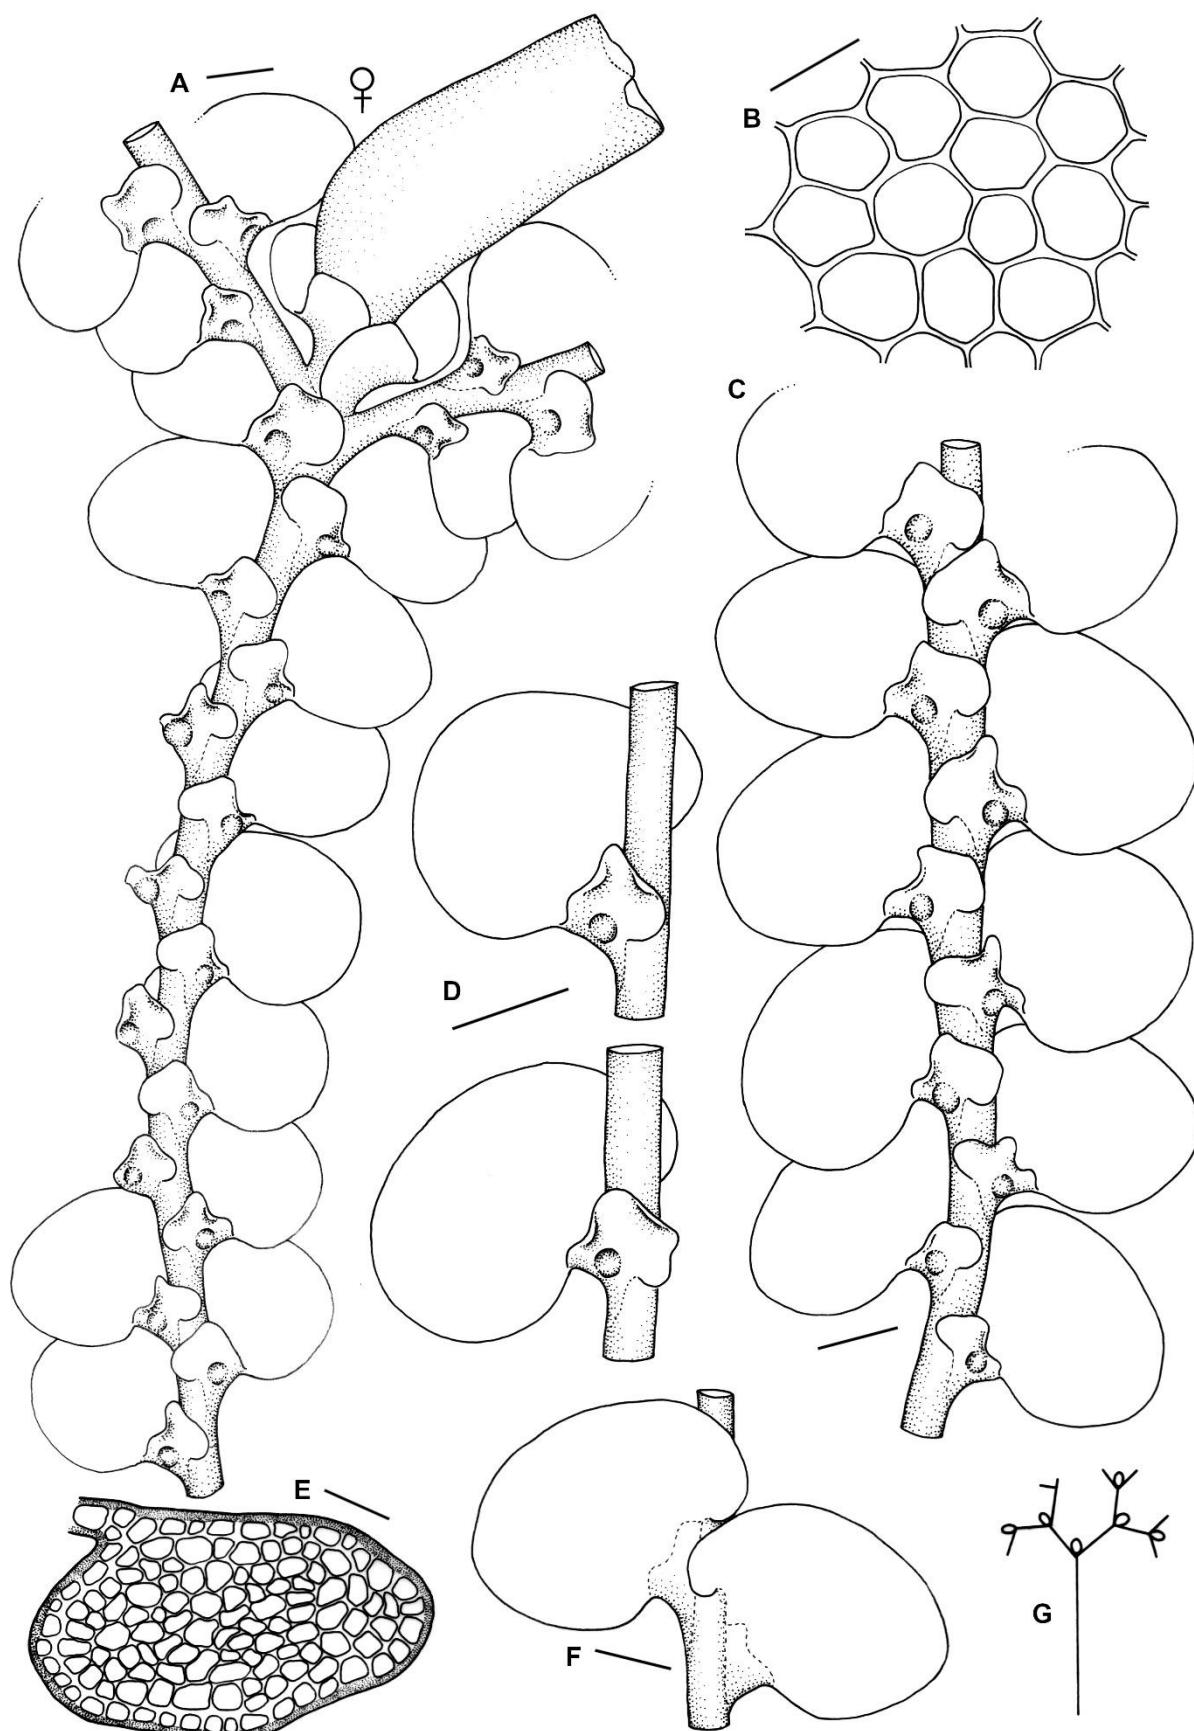

Figure 33. A-G. *Radula xalapensis* - A. Habit with gynoecia. B. Median leaf cells. C. Habit. D. Leaves. E. Cross section of a stem. F. Habit, dorsal view. G. Cladograph of fertile plants (open ellipse= gynoecia with perianth) (A, C-D, F= 500 μ m; B= 25 μ m; E= 50 μ m; A-G from RB347475).

TAXONOMIC NOTES: *Radula xalapensis* is characterized by (1) plants robust (2500–4000 µm wide), regularly 1–2-pinnate (see Gradstein et al. 2016); (2) leaves widely spreading to squarrose, distant to contiguous, ovate to falcate-ovate; (3) lobules distant to contiguous, (sub)quadrate, base rounded and sometimes slightly coiled, covering 3/4 to fully overlapping the stem, free margin and distal margin incurved, rarely plane, apex rounded to obtuse, and keel straight to concave.

In the large habit and regularly 1–2-pinnate branching *R. xalapensis* resembles *R. voluta*, but the lobules in the latter species are larger, imbricate and the base of the lobule is much more expanded, extending far across and beyond the stem and being more strongly coiled.

EXAMINED SPECIMEN: **Brazil.** RIO DE JANEIRO: Parque Nacional do Itatiaia, riacho de uma propriedade particular a direita da estrada para Maromba e Véu de Noiva, na estrada logo após a entrada da administração, sobre pedra a beira do riacho, 900 m, 10 April 2000, Costa & Gradstein 3724 (RB).

TYPE: Brazil, São Paulo, São Luiz do Piraitinga, Parque Estadual da Serra do Mar, Núcleo Santa Virgínia, “trilha do Corcovado, Mata Atlântica, sobre folhas,” 23°24'07"S, 45°11'33"W, 981 m, 11 June 2013, Peralta & Carmo 14155 (holotype: SP-438627!).

Dioicous. PLANTS 1–2(–2.5) mm wide, yellowish-green to pale green in herbarium, densely regularly to irregularly pinnate. STEMS in cross section with ca. 30 thick-walled epidermal cells surrounding ca. 60 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls colorless, trigones lacking. LEAVES widely spreading, imbricate, slightly convex, ovate, 0.7–1.2 mm long, 0.5–0.8 mm wide, dorsal base rounded, auriculate, overlapping the stem, apex obtuse to subacute, margin plane, entire; marginal cells subquadrate to isodiametric, 12–17 × 10–12 µm, median and basal cells isodiametric to elongate, 12–22 × 10–15 µm, cell walls thin, trigones small to lacking, cuticle smooth. LOBULES distant to contiguous, rarely imbricate, subquadrate, 0.3–0.6 mm long, 0.25–0.5 mm wide, 1/2–2/5 the lobe length, strongly inflated at rhizoid area and along the keel, insertion line arched, base plane, rounded to obtuse, covering 1/3 to fully overlapping the stem, free margin plane, straight to sinuate, apex rounded to obtuse, distal margin ± straight; keel conspicuously convex, spreading at angles of 60° with the stem. RHIZOIDS colorless to brown, numerous. GAMETOECIA and VEGETATIVE REPRODUCTION not observed (Oliveira-da-Silva & Ilkiu-Borges 2020).

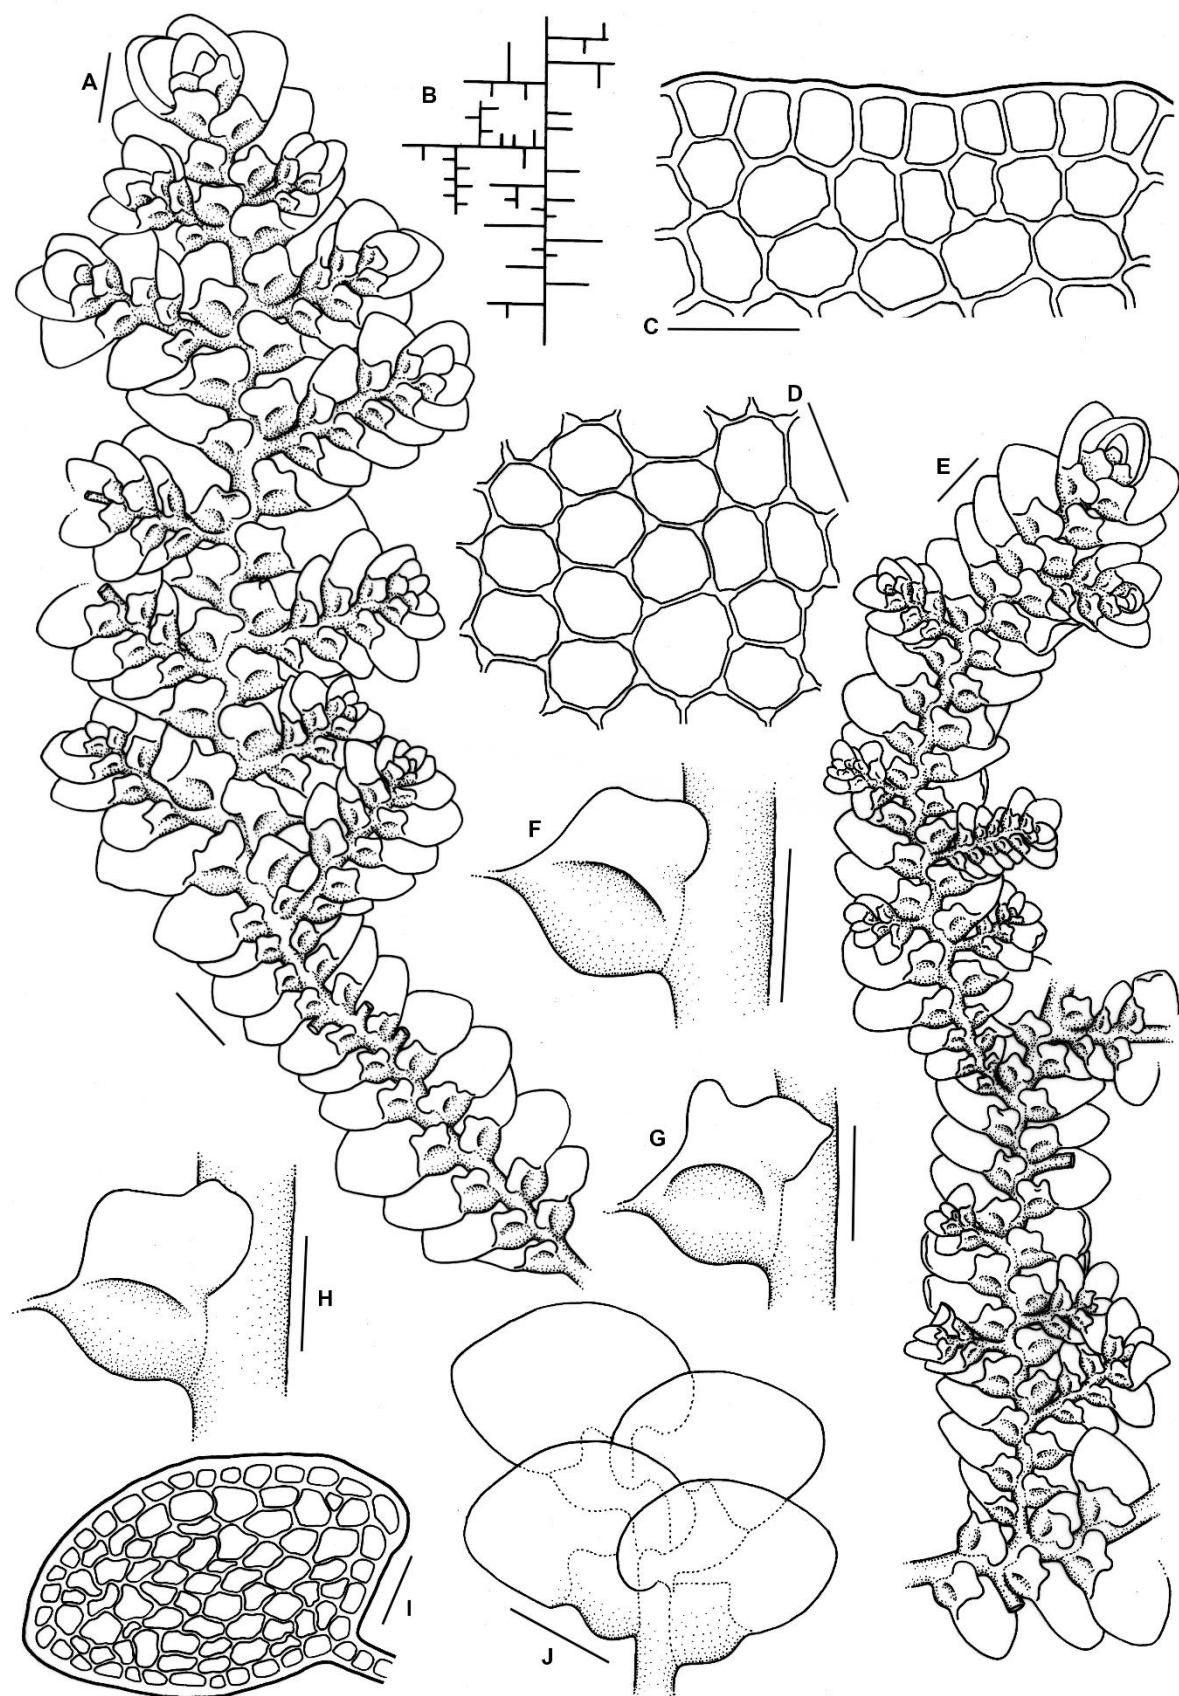

Figure 34. A-J. *Radula yamadae*. A, E. Habit. B. Cladograph of plants. C. Marginal leaf cells. D. Median leaf cells. F-H. Lobule. I. Cross section of a stem. J. Habit, dorsal view (A, E, J= 500 μm ; C, D= 25 μm ; F-H= 250 μm ; I= 50 μm ; A-J from the SP438627).

DISTRIBUTION AND HABITAT: Brazil. The species is known from Paraná and São Paulo, growing on living leaves and rock in Atlantic forest, at 1000–1200 m elevation

TAXONOMIC NOTES: *Radula yamadae* is diagnosed by (1) plants densely branched; (2) stem consisting of ca. 90 cells in cross section (epidermal plus medullary cells); (3) leaf lobes ovate with obtuse to subacute apex; (4) cell with small trigones; (5) lobules distant to contiguous, rarely imbricate, subquadrate, 1/2–2/5 the lobe length, base rounded to obtuse, covering 1/3 to fully overlapping the stem, keel conspicuously convex, strongly inflated at rhizoid area and along the keel (Oliveira & Ilkiu-Borges 2020). The species is close to *R. longiloba* (see comments under the latter species).

ADDITIONAL EXAMINED SPECIMENS: **Brazil.** PARANÁ: Morretes, Parque Estadual do Marumbi, trilha vermelha, caminho para a ponta do tigre, Mata Atlântica com afloramentos rochosos, sobre rocha, 25°26'55"S, 48°54'54"W, 1200 m, 22 July 2014, Peralta et al. 15877 (SP, MG).

Radula yanoella R.M.Schust., Phytologia 56: 72. 1984.

Fig. 35

TYPE: Brazil, Amazonas, Rio Negro, near São Gabriel, from Igarapé Arabú on Rio Curicuriari to summit of Serra Curicuriari, 00°20'S, 66°50'W, 450 m, 9–12 July 1979, R. M. Schuster 79-15-627#2 (neotype: NY-00840786!, designated here), ibid., 79-15-627 (isoneotype: NY-00840787!).

Dioicous. PLANTS 0.9–1.1 mm wide, green to pale green in herbarium, consisting of a small, irregularly pinnate, rosette-like thallus with leafy shoots sprouting from the thallus margins, leafy shoots usually unbranched. THALLUS to ca. 1 µm wide, of 1 layer of rectangular cells, 20–40 × 6–20 µm, thallus margins irregularly rounded, entire, producing leafy branches, cell walls thick, trigones lacking, cuticle smooth. STEMS in cross section with 10–13 thin-walled epidermal cells surrounding 4–5 thin-walled medullary cells, epidermal and medullary cells of the same size, epidermal and medullary cell walls colorless, trigones lacking. LEAVES obliquely to widely spreading, contiguous to subimbricate, slightly convex, ovate to falcate-ovate, 0.55–0.75 mm long, 0.4–0.55 mm wide, dorsal base rounded, not overlapping the stem, apex rounded, margin plane, entire to crenulate when with gemmae; marginal cells subquadrate to isodiametric, 10–12 × 7–10 µm, median and basal cells isodiametric, 12–20 µm in diam., cell walls thin, trigones small to lacking, cuticle smooth. LOBULES distant, subquadrate to ovate-subquadrate, 0.15–0.3 mm long, 0.1–0.15(–0.2) mm wide, 1/4–1/3 the lobe length, inflated at rhizoid area, insertion line ± arched, base plane, ± rounded, covering 1/3–1/2 the stem, free margin plane, straight, apex rounded to obtuse, distal margin straight; keel ± straight to convex, spreading at angles 45–50° with the stem. Rhizoids colorless, numerous on a pronounced mammilliform swelling. ANDROECIA terminal on

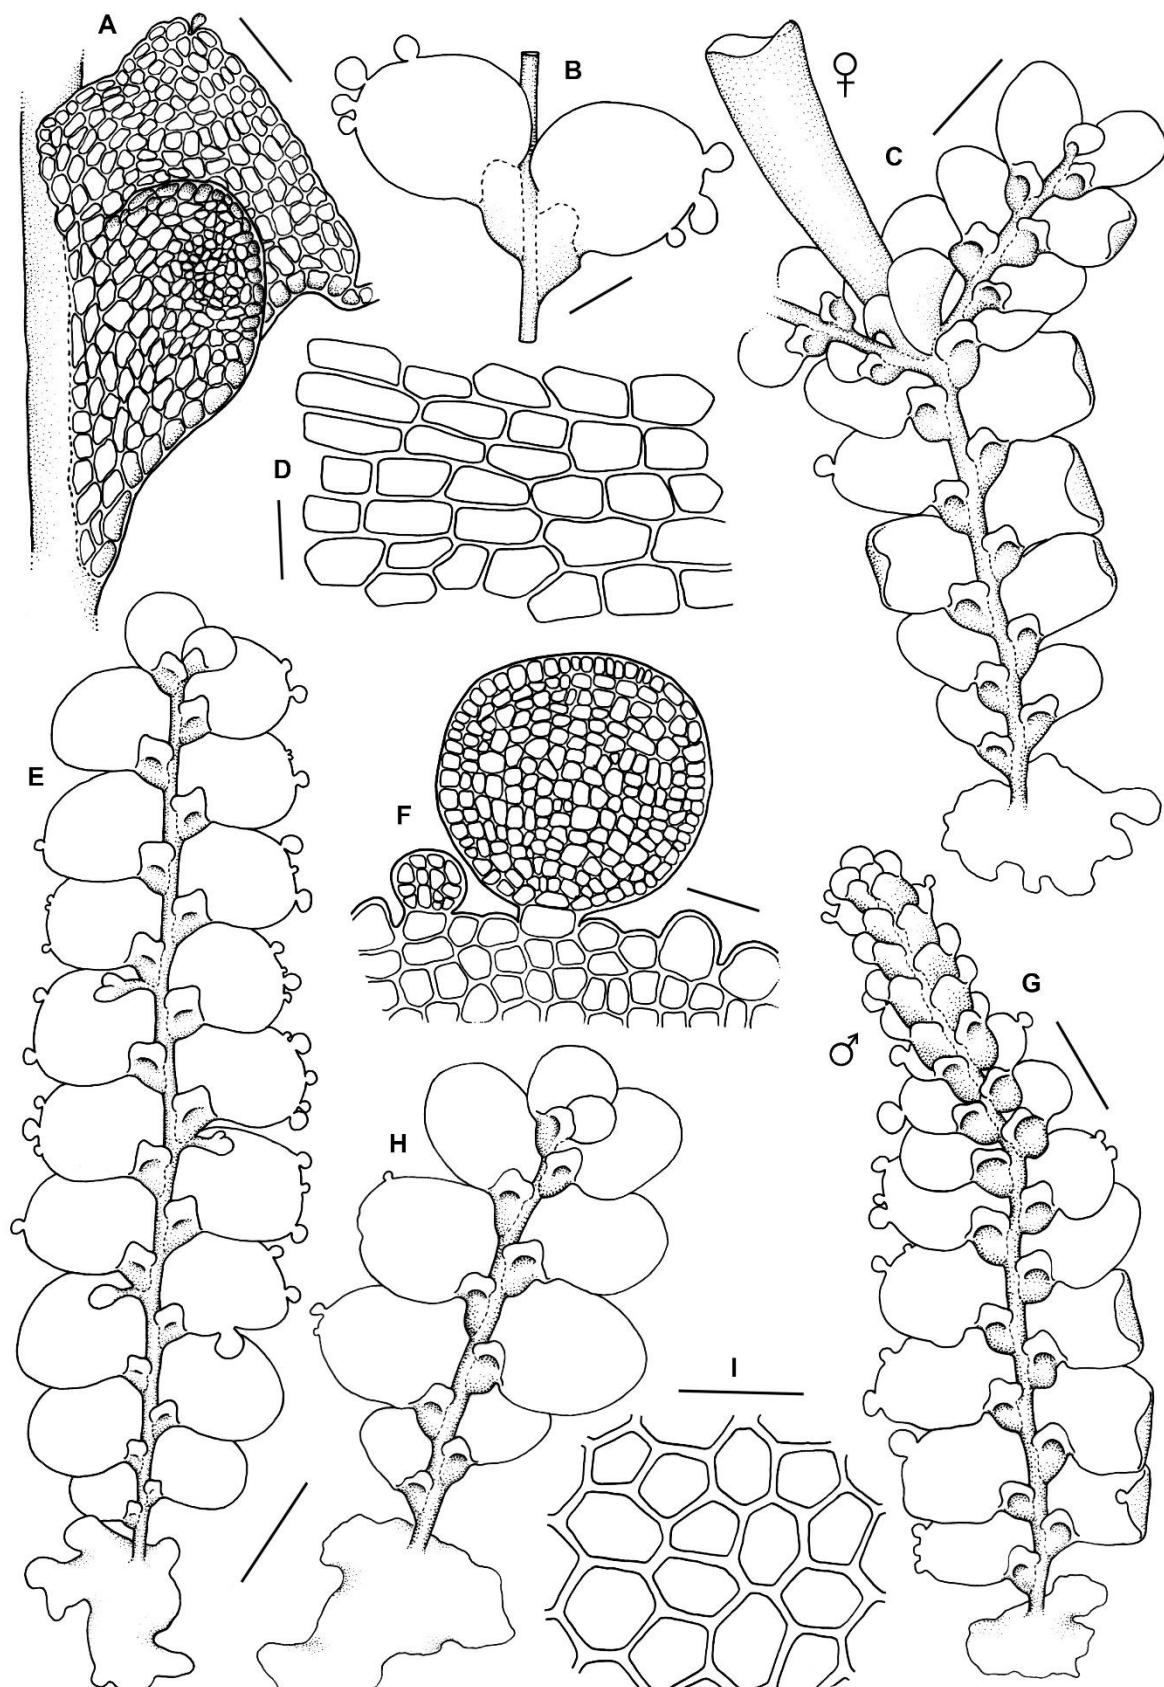

Figure 35. A-I. *Radula yanoella* - A. Lobule. B. Habit, dorsal view. C. Habit with gynoecia. D. Cells of thallus. E, H. Habit. F. Gemmae. G. Habit with androecia. I. Median leaf cells. (A= 50 μ m; B= 250 μ m; C, E, G, H = 500 μ m; D, F, I= 25 μ m; A, D, H-I from neotype NY00840786; B, C, G from HBRA8439; E-F from SP182539).

long branches, with 3–6 pairs of bracts, 0.4–0.5 mm wide; bracts ovate, 0.34–0.38 mm long, 0.14–0.2 mm wide, apex rounded, margin plane, entire, lobule ovate, ca. 5/6 of lobe length, base ± rounded to straight, free margin straight, apex rounded. GYNOECIA on long branches, with two innovations; bracts oblong-ovate, ca. 0.7 mm long, 0.4 mm wide, apex rounded to obtuse, margin plane, entire, lobule oblong, ca. 1/2 of lobe length, apex rounded to obtuse. PERIANTHS subcylindrical, ca. 1.8 mm long, ca. 0.48 mm wide at apex, mouth entire, undulate. VEGETATIVE REPRODUCTION by small discoid gemmae, ca. 100 µm in diam., produced on leaf margins.

ADDITIONAL DESCRIPTION AND ILLUSTRATION: Schuster (1991, p. 59–61, Fig. 2), Gradstein & Ilkiu-Borges (2009, p. 41–43, Fig. 23D–H).

DISTRIBUTION AND HABITAT: Costa Rica, Ecuador, French Guiana, Brazil. In Brazil *Radula yanoella* has for a long time been known from the Amazon basin (Amazonas, Pará); here the species is newly reported from the Atlantic Forest region (Rio de Janeiro) where it seems to be very rare. The species grows on living leaves at 400–600 m elevation.

TAXONOMIC NOTES: *Radula yanoella* is a neotenic species characterized by (1) plants small, epiphyllous, consisting of a rosette-like thallus (=persistent protonema) with short leafy shoots sprouting from the thallus margins; (2) leaf lobes with small discoid gemmae on the margins. *Radula yanoella* somewhat resembles *R. flaccida* and *R. stenocalyx* but the latter species lack a persistent thallus (see also comments under these species).

Radula yanoella was described by Schuster (1984) based on a specimen collected in Serra Curicuriari, Amazonas, Brazil, and numbered Schuster 80-1691 in the protologue. Schuster (1991) indicated that the plants were growing on fern fronds and that the type was deposited in NY with a duplicate to his personal herbarium (currently in F). However, this collection was not found in F or NY. As Schuster's collections are usually numbered by year of collecting and as the expedition to Serra Curicuriari took place in 1979 (Costa et al. 2017), the collection number is presumably erroneous. Instead, the specimen in NY of *R. yanoella* labelled “isotype” (NY-1021204!) bears the number Schuster 79-15-691 (with a note indicating that this is the correct number of the type). However, this specimen contains only *R. flaccida*, not *R. yanoella*, and the substrate is not fern frond. According to Dr. Matt von Konrat (pers. com.), the duplicate of this specimen in the Schuster herbarium contains only various species of Lejeuneaceae, no *Radula*. Nonetheless, studying further material in NY from the Curicuriari expedition, two duplicate specimens were found containing *Radula yanoella* growing on a fern frond, Schuster 79-15-627 (NY-00840787!) and 79-15-627#2 (NY-00840786!). Both contain an annotation in Dr. Schuster's handwriting, indicating that they are the type of *Radula yanoella*. As the specimen with the original collection

number cannot be found, the specimen 79-15-627#2 is designated here as neotype (ICN Art. 9.8) and 79-15-627 as isoneotype.

SELECTED EXAMINED SPECIMENS: **Brazil.** AMAZONAS: São Gabriel, Serra Curicuriari, from Igarapé Arabú on Rio Curicuriari to summit, 00°20'S, 66°50'W, 450 m, 9 July 1979, Schuster 79-15-725 (INPA). PARÁ: Oriximiná, ESEC do Grão Pará, Serra do Acari, 407–600 m, 28 August 2008, Pietrobom & Maciel 7838 (HBRA). RIO DE JANEIRO: Resende, Parque Nacional do Itatiaia, junto do Véu de Noiva, 20 June 1983, Yano & Santos 7481 (SP).

Excluded records

Radula elliotii Castle: This species was recorded from Brazil by Schäfer-Verwimp & Vital (1989) based on a specimen from Serra do Mar, São Paulo State (Schäfer-Verwimp 7634, SP-386118!). Our study of the specimen revealed that it belongs to *R. angulata*. Further specimens in Brazilian herbaria identified as *R. elliotii* proved to be *R. javanica* or *R. pocsii*.

Radula varilobula Castle: The species was recorded by Schäfer-Verwimp & Vital (1989) from Poços de Caldas, Minas Gerais (Schäfer-Verwimp & Verwimp 7030, SP-386069!). The record – the only report of the species from Brazil – was confirmed by Yano (1995) and Yamada (2003). Our study of the material revealed that it belongs to *R. schaefer-verwimpii*.

Radula wrightii Castle: All collections from Brazil identified as *R. wrightii* proved to belong to *R. pallens* or *R. javanica*. *Radula wrightii* is apparently restricted to Cuba (Castle 1959a).

Doubtful records

Radula marginata Gottsche, Lindenb. & Nees: This species, endemic to New Zealand, was first reported for Brazil from Teresópolis, Rio de Janeiro State, by Oliveira e Silva & Feitosa (1997); the collection was not examined and it is probably a misidentification (see Reiner-Drehwald 1994, Yamada 2003). The description and illustration of Oliveira e Silva & Feitosa (1997) leads to *Radula ligula*, similar *R. marginata* by ligulate lobules and the marginal leaf cells differentiated.

Radula microloba Gottsche: This Chilean species was first reported for Brazil from Rio Grande do Sul by Lindman (1906); the collection was not found. All further collections from Brazil identified as *R. microloba* proved to belong to *R. pallens* or *R. javanica*.

Radula saccatiloba Steph.: First recorded for Brazil by Dusén (1903) from Rio de Janeiro; the specimen was not located and further collections from Brazil identified as *R. saccatiloba* belong to *R. javanica*, *R. decora* or *R. subinflata*. The species is known from Central America, West Indies and northern Andes.

Acknowledgments

Thanks are due to the curators and collection managers of herbaria for the loan of *Radula* specimens: ALCB (Cid J. P. Bastos), BM (Leonard T. Ellis), G (Philippe Clerc and Isabella Valette), HBRA (Marcio Pietrobom-Silva), ICN (Mara Rejane Ritter), INPA (Michael Hopkins), JE (Jörn Hentschel), MG (Pedro Lage Viana), NICH (Tomoyuki Katagiri), NY (Barbara Thiers), RB (Rafaela Forzza), S (Arne Anderberg and Annelie Jörgensen), SP (Denilson Peralta), and UFP (Marlene Barbosa). A special thanks to Barbara Thiers and Rafaela Forzza for logistical support during the visit of the first and third author to the herbaria of NY and RB, respectively. We furthermore express our gratitude to William R. Buck for advice on the typification of *Radula yanoella*; to Laura Briscoe for constant and kind support during the visit to the herbarium of NY; and to Denilson Peralta by sending numerous specimens on loan as well as photographs of *Radula* specimens deposited in herbarium SP; to Matt Renner for advice on the taxonomy of *Radula renneri*; and to Anders Hagborg and an anonymous reviewer for comments and corrections on the manuscript. Thanks are also due to the Programa de Pós-Graduação em Ciências Biológicas – Botânica Tropical, from Museu Paraense Emílio Goeldi and Universidade Federal Rural da Amazônia; to the National Council for Scientific and Technological Development (CNPq) for the MSc fellowship grant of the first author (process n°132059/2018-5), and for the productivity fellowship grant of the third author (process n°302374/2016). This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001.

CONSIDERAÇÕES FINAIS

Neste estudo foram reconhecidas 31 espécies e duas variedades de *Radula* para o Brasil, baseados na análise dos tipos nomenclaturais e em 900 amostras depositadas em herbários brasileiros e estrangeiros. Foram descritas três espécies novas (*Radula bahiensis*, *R. renneri* e *R. yamadae*) e uma variedade nova (*R. fendleri* var. *paroica*) para a ciência. *Radula bahiensis* e *R. fendleri* var. *paroica* foram descritas em um artigo submetido para a revista Phytotaxa (Capítulo I), *R. yamadae* para a revista Nova Hedwigia (Capítulo II) e *R. renneri* foi descrita na revisão submetida a Nova Hedwigia (Capítulo III).

Foram identificadas quatro três ocorrências para o Brasil: *Radula longiloba*, *R. punctata* e *R. xalapensis*. Além disso, três espécies foram excluídas da lista de *Radula* no Brasil (*Radula elliotii*, *R. varilobula* e *R. wigritii*), assim como três espécies foram classificadas como duvidosas (*R. saccatiloba*, *R. microloba* e *R. wrightii*). Duas espécies foram confirmadas para o Brasil (*R. subinflata* e *R. pseudostachya*), visto que as suas ocorrências vinham sendo negligenciadas em importantes listas da brioflora brasileira.

Foram designados, neste estudo, lectótipos para as espécies *R. flaccida*, *R. epiphylla* (=*R. flaccida*), *R. quadrata*, *R. stenocalyx*, *R. tectiloba* e *R. tenera* além de um neótipo para *R. yanoella*. A espécie *Radula obovata* é proposta como sinônimo de *R. pallens*.

Esses resultados mostram a importância de estudos taxonômicos desta natureza para ampliar o conhecimento das espécies de briófitas que ocorrem no Brasil e em outras partes do globo.
